(8:35 a.m.)

WELCOME - OUTLINE PURPOSE AND OBJECTIVES OF WORKSHOP

DR. SUNDLOF: Good morning. If I could ask everybody to please take their seats, we can begin this morning's session.

(Pause.)

DR. SUNDLOF: All right. Good morning, everyone, and welcome to CVM's second workshop on antimicrobial resistance. It is really great to see the turn out that we have here today. For the next three days we are going to be discussing some issues that are very important to CVM and to the industry, and so, I hope everybody is refreshed and ready to go here.

The purpose of the meeting is to discuss the appropriate design of pre-approval studies. We talked about pre-approval studies for a long time in the context of antimicrobial resistance, and we need to consider in the discussion today both the rate and the extent of resistance development in the appropriate microbiological organisms and also look at the issue of pathogen load, which is also a critical factor in pre-approval testing.

(Slide.)

DR. SUNDLOF: So the meeting's objectives are to obtain scientific input on these issues. These are very

1 complex issues that are meant to give us some kind of
2 predictive value in assessing what will happen with the drug
3 after the approval process.

4 And again, it is a scientific and complex issue, so
5 we need as much as input as possible, and we would like to
6 hear a lot of different perspectives and a lot of different
7 alternatives hopefully that will emerge from this discussion.

8 (Slide.)

9 DR. SUNDLOF: Our goals are to get all the ideas
10 out on the table. We want to hear as many as we can. We
11 want to listen to our experts and ask them lots of questions.
12 We want to hear from the public. We want to hear how they
13 view some of the issues we will be dealing with.

14 We want to discuss these issues in further depth in
15 the breakout sessions, which will occur tomorrow afternoon
16 and Thursday morning. So the breakout sessions will give
17 everybody a chance to participate in the discussion. And we
18 want to do a lot of brainstorming. We want, again, people to
19 come away from this with a greater understanding and
20 appreciation than what they came here with. So lots of good
21 ideas, hopefully, will emerge from this meeting.

22 I just want to make a statement right now that it
23 is not the intention to come to a final decision on pre-
24 approval studies at this meeting. This is not a meeting that
25 is intended to reach a consensus opinion on what the exact

1 proper study should be.

2 It is one in which we are going to try to get as
3 many good ideas out as possible. Those ideas will then form
4 the basis for further comment and finalization of what we
5 will consider eventually as the proper design for these
6 pre-approval studies.

7 (Slide.)

8 DR. SUNDLOF: Just to give a little bit of
9 background, in November of 1998 we issued a guidance
10 document, number 78, which says that based on what we
11 perceive to be the potential public health threat from
12 antimicrobial resistance development, we believed it is
13 necessary to consider the potential human health impact of
14 microbial effects associated with the use of animal drugs.

15 To do that, we were looking at two different
16 issues. Resistance, and also, we wanted to consider pathogen
17 load that may increase as the result of using antimicrobials.
18 So that was guidance document number 78 in November of '98.

19 In December of '98 we issued a paper that we have
20 referred to as the framework document, and I am sure
21 everybody is familiar with that document at this time. It
22 states FDA's position; that the regulatory system for
23 antimicrobials for use in food animals should be modified to
24 address microbial safety. Prior to that, with the exception
25 of a few cases, we had not considered that in the assessment

1 of safety.

2 The framework includes a concept of using
3 pre-approval studies to evaluate the safety of the proposed
4 products, and so pre-approval studies was a critical element
5 in the framework document, and that is what this workshop is
6 about; to really focus in on the pre-approval studies.

7 (Slide.)

8 DR. SUNDLOF: Just briefly, we will go through the
9 agenda; what we can expect in the next three days. First of
10 all, this morning we will have an overview of antimicrobial
11 use patterns from a number of the producer organizations. So
12 we will look at poultry versus ruminants versus swine, et
13 cetera, and how antimicrobials may be used in those
14 practices.

15 We will also hear a little bit about drug discovery
16 and what is involved on the industry side on drug
17 development. And finally, just to give everybody a solid
18 background, we will have some presentations from people
19 within CVM to explain the regulatory process in general, and
20 specifically then, how it applies to the regulation of
21 antimicrobial drugs for food producing animals.

22 We will also have a presentation based on what we
23 refer to as "558.15" drugs, and those are the sub-therapeutic
24 antimicrobials for which CVM has, for a number of years,
25 required pre-approval studies. So that can serve as a kind

1 of background for looking at what we have done in the past,
2 where we feel the strengths of those studies were and where
3 some of the weaknesses potentially lie. From there, it may
4 be easier to try and move forward.

5 (Slide.)

6 DR. SUNDLOF: This afternoon we will finish session
7 one. Again, there will be some talks from CVM people on the
8 regulatory process, and we will have a discussion of some
9 general concept of microbial safety and assessment. And we
10 will be listening to some experts, some people that have got
11 some experience and some ideas on how these studies might
12 best be performed and the discussion of some of the specific
13 factors to consider regarding resistance and pathogen load.

14 And then we will begin session two, which is more
15 conceptual perspectives. We want to get different
16 perspectives on how we might approach the issue of
17 pre-approval studies for microbial safety. So on Wednesday
18 morning then we will finish up those presentations.

19 And then, the people who have been talking this
20 afternoon and tomorrow morning will sit on a panel and will
21 have an open public meeting and a panel discussion tomorrow
22 morning on some of the things that we have heard to date.

23 (Slide.)

24 DR. SUNDLOF: And then, on Wednesday afternoon, we
25 will begin the breakout sessions. Those breakout sessions,

1 if you look at your agenda, are grouped according to the
2 species of interest. So they are species based breakout
3 groups and people will be allowed to go to whichever of those
4 breakout sessions that they feel is of most interest to them.

5 We have provided some questions, and they are in
6 your agenda. The questions we won't go over at this time
7 because a lot of those questions you really won't be able to
8 have a good idea of how to answer until you have heard the
9 discussions that have led up to the breakout sessions.

10 You will have an opportunity during the comment
11 period on Wednesday afternoon to add additional questions or
12 raise additional concerns for discussion during the breakout
13 session.

14 (Slide.)

15 DR. SUNDLOF: Then, on Thursday, we will finish the
16 breakout sessions and the chairs or the moderators of those
17 breakout sessions will begin to prepare the reports. And
18 then, on Thursday afternoon, we will have a presentation of
19 all of the breakout groups and then further discussion, and
20 then we will talk about next steps based on what we have
21 heard during the course of the entire three days.

22 (Slide.)

23 DR. SUNDLOF: Okay. But it doesn't end there. It
24 doesn't end Thursday. We still think that this is a
25 continuing, ongoing process. It begins here, but it

1 continues on, and we have opened up a docket and that is the
2 number of the docket so that additional comments can be sent
3 to FDA. That is the docket number that you refer to, and we
4 will take all those comments into account.

5 Additionally, the transcript of this workshop will
6 be made available. We will have a full transcript on CVM'S
7 web site, and there you have our web site address. And then
8 the final thing I need to do is just a few little
9 housekeeping details.

10 Refreshments will be available during the breaks,
11 but because we want to have as productive a meeting as
12 possible, we would ask everybody to, please, try to return
13 from the breaks on time so that we can keep on schedule.
14 Lunches will be on your own. There will be a short reception
15 on Wednesday at 5:30 in the evening.

16 And if you have any questions or need anything
17 during the next three days, the two people that are sitting
18 out there at the table outside of this room are Alita
19 Sinderlar and Linda Cowatch, and they will be glad to assist
20 you if you have any problems at all.

21 So, those are my opening remarks. I would now like
22 to turn the program over to the moderator of the first
23 session, and that is Dr. Claire Lathers. Dr. Lathers is
24 relatively new in the Center for Veterinary Medicine. She is
25 our office director in the Office of New Animal Drug

1 Evaluation where the studies eventually will be evaluated.
2 So, Claire, I will turn it over to you.

3 CHAIRWOMAN LATHERS: Thank you, Steve. Welcome to
4 the Center for Veterinary Medicine's workshop. We will be
5 looking at pre-approval studies and asking the question:
6 Antimicrobial resistance and pathogen load; how do we best
7 design our protocols?

8 On behalf of the Office of the New Animal Drug
9 Evaluation and the center, I would like to begin by thanking
10 all of those who have contributed to the effort of making
11 this workshop a success: Bill Flynn, Dave White, all of the
12 members of the CVM pre-approval protocol group. They have
13 spent a lot of time discussing possibilities, and now they
14 are here to share and to listen with you and your ideas.

15 And Blue has assisted, Linda Towlson, Steve
16 Sundlof, Sharon Thompson, and indeed, all of the senior
17 management team. And finally, Anita Sinderlar and Linda
18 Cowatch are the people that are making the actual workshop
19 happen, if you would, in terms of the mechanics.

20 So, with the first speech, we will now begin our
21 discussion of the appropriate designs for the pre-approval
22 studies to evaluate the microbial effects of antimicrobial
23 drugs intended for use in food producing animals and ask the
24 question: How do we address the rate and the extent of
25 resistance development and the changes in the number of

1 enteric bacteria in the animal's intestinal tract that can
2 cause human illness?

3 Our first speaker to begin to address these
4 questions is Dr. Gates Riddell. He is a professor in large
5 animal surgery and medicine at Auburn University, he is the
6 past president of the American Association of Bovine
7 Practitioners, he is a member of AVMA's drug advisory
8 committee and a member of the AABP's committee on
9 pharmaceutical and biological issues. Dr. Riddell.

10 **ANTIBIOTIC USE IN RUMINANTS - AN OVERVIEW**

11 **By Dr. Gatz Riddell**

12 DR. RIDDELL: Thank you, Dr. Lathers. I appreciate
13 the opportunity to be able to bring some perspective from the
14 ruminant species this morning. I would like to start off my
15 comments by talking about some of the preparatory steps
16 towards considering the use of antibiotics in ruminants.

17 There are numerous tools available to animal
18 agriculture, which can be implemented to maintain animal
19 health today. These include well-researched nutritional
20 guidelines, vaccines both old and new to aid in the
21 prevention of disease, a greater understanding of appropriate
22 housing designs for various classes of animals and proven
23 protocols for the integration of these tools in preventive
24 medicine programs.

25 However, there are also numerous uncontrollable

1 variables which can impact animal health and which can
2 compromise the effectiveness of health maintenance protocols.
3 Antibiotics are and will continue to be an important and
4 necessary tool for the treatment of certain infectious
5 diseases and prevention of pain and suffering resulting from
6 these diseases.

7 It is difficult, if not impossible, to prevent
8 exposure to disease pathogens. For example, the bacteria,
9 group of bacteria, that have been associated with causing
10 bovine respiratory disease.

11 (Slide.)

12 DR. RIDDELL: Some of these infectious agents are
13 found in regionally select areas of the United States.
14 Others may require the presence of specific animal
15 populations, while others may be universally found in the
16 environment, regardless of the presence or concentration of
17 animal agriculture.

18 (Slide.)

19 DR. RIDDELL: Variables which can place animals at
20 risk for developing disease subsequent to exposure to these
21 bacterial pathogens include variation in individual animal
22 susceptibility to disease and response to effective
23 vaccination protocols. There will be environmental stressors
24 that are truly uncontrollable, such as weather, drought and
25 other ambient conditions.

1 There will be life cycle events that are stressors
2 of themselves, such as calving in lambing for the yew, and
3 there will be management stressors, such as diet changes,
4 which are important as we take this monogastric animal at
5 birth to a ruminant at maturity, and transportation.

6 In addition to the potential for bacterial
7 pathogens to cause disease, there are numerous viral agents
8 which can alter local or systemic immune system function and
9 open the door for secondary bacterial infection.

10 (Slide.)

11 DR. RIDDELL: For those diseases of bacterial
12 origin, the only recognized therapy may require the use of
13 properly selected, dosed and administered antibiotics. It is
14 impossible within the scope of this short presentation to
15 describe all the diseases scenarios for which the use of
16 parenteral,

17 (Slide.)

18 DR. RIDDELL: Invasive surgical procedures will be
19 performed on ruminant animals under field conditions which
20 can place the animal at risk for bacterial wound infections.

21 Examples of some of these field procedures would include
22 exploratory abdominal surgeries and cesarean sections
23 performed because of obstetrical difficulties encountered in
24 an animal which cannot be transported to a surgical facility.

25 Beyond that, even excellent surgical facilities

1 themselves cannot prevent all bacterial incisional
2 complications. Additionally, ruminant animals may, by their
3 nature, suffer traumatic injuries which can be complicated by
4 secondary bacterial wound infections.

5 The former circumstance, surgical procedures, will
6 require systemic antibiotics to prevent bacterial infection
7 following contamination, and the latter, the traumatic
8 injury, may require a full return to health following the
9 development of a bacterial infection.

10 (Slide.)

11 DR. RIDDELL: There are certain conditions under
12 which the potential for the development of a bacterial
13 infection is increased due to environmental transport,
14 management, housing or life cycle circumstances. Respiratory
15 disease in cattle or lambs entering the feed lot are an
16 example of this.

17 As with many diseases seen in agriculture, the
18 causes of respiratory disease outbreaks are considered truly
19 multi-factorial. The stress associated with transportation
20 and increased exposure risk due to the commingling of newly
21 introduced and the potentially immuno suppressive effects of
22 at least one upper respiratory virus all tend to predispose
23 to bacterial disease.

24 Now, there are numerous antibiotics on the market
25 today which are labeled for treatment of bovine respiratory

1 disease, each of which can be effective against the disease,
2 but none of which will be universally effective. Therefore,
3 the need for the current armamentarium and increasing our
4 armamentarium in this area.

5 For this reason, the wide range of therapeutic
6 options will allow a practitioner to base treatment upon
7 diagnostic microbiology and previous experience, with
8 clinical judgment thrown in, and make treatment adjustments
9 where needed.

10 (Slide.)

11 DR. RIDDELL: Another bacterial condition which is
12 life cycle related and which will respond to antibiotic
13 therapy is a life-threatening uterine infection, which
14 develops in the first three to 10 days after a cow has a
15 calf. This condition, known as a toxic or septic metritis,
16 can make an animal severely ill, may result in her death or
17 render her reproductively unsound in future years.

18 In years past, intrauterine antibiotic therapy has
19 been utilized, to a great degree, to treat this condition.
20 Research on the type and location of problematic bacteria now
21 suggests that systematic antibiotics, rather than
22 intrauterine, are markedly more effective.

23 Monitoring protocols have been developed and
24 implemented on many herds to develop infections early in the
25 stage of the disease, which involves something as simple

1 monitoring, daily, the body temperature of the animal.

2 These protocols have been able to direct much more
3 specific and limited antibiotic use because of early
4 intervention. These use of these protocols allowed treatment
5 to be initiated earlier in the disease in those animals which
6 are going to develop metritis, thereby enhancing the
7 therapeutic success rate and minimizing the overall use of
8 antibiotics because of early intervention.

9 (Slide.)

10 DR. RIDDELL: Lameness is a common condition
11 diagnosed in both beef and dairy cattle. There are specific
12 bacterial conditions, such as necrotizing pododermatitis, a
13 condition commonly known as foot rot, which occurs when
14 certain types of anaerobic bacteria gain entry into the soft
15 tissues of the lower leg and feet of cattle. These
16 infections respond readily to the use of appropriate systemic
17 antibiotics.

18 More common causes of lameness are conditions such
19 as sole bruises and sole ulcers, as you see in the picture
20 here, for which antibiotic therapy is of little benefit or no
21 benefit. Diagnostic and treatment protocols for lameness in
22 cattle have been developed which direct therapy to the
23 specific condition, including antibiotics where necessary and
24 appropriate.

25 (Slide.)

1 DR. RIDDELL: Trained, experienced veterinary
2 practitioners are able to evaluate disease outbreaks, apply
3 well researched principles and make predictions as to when
4 disease outbreaks may potentially spread to other unaffected
5 animals. An excellent example of this type of outbreak is
6 bovine respiratory disease.

7 The multi-factorial nature of this disease and the
8 many predisposing factors have already been outlined. When
9 the predisposing factors are present and unaffected animals
10 have been placed at risk, the metaphylactic or prophylactic
11 use of antibiotics in cattle and feeder lambs at risk for the
12 development of respiratory disease of bacterial origin can
13 prevent the outright development of disease in large
14 populations of animals.

15 Studies have demonstrated that the appropriate
16 application of the principles of metaphylactic therapy can
17 reduce the overall use of antibiotics in certain groups of
18 animals.

19 (Slide.)

20 DR. RIDDELL: Another example of a preventive
21 strategy which involves the use of antibiotics would be the
22 use of intramammary antibiotics in the dairy cow entering the
23 dry period, a time in her life cycle in which there is a
24 documented increase in risk for the development of bacterial
25 mastitis.

1 When a mature lactating cow reaches seven months of
2 pregnancy, she is dried off and she enter her dry period.
3 This is a time where she is not milked to allow regeneration
4 of the secretory cells of the mammary gland before she enters
5 her subsequent lactation with the birth of her next calf.

6 The two times that you can see on this graph of
7 greatest risk for the development of a new intramammary
8 infections during the entire lactation cycle are the first
9 two weeks and the last two weeks of the dry period. In
10 addition, lactating dairy cows may enter the dry period with
11 a subclinical bacterial mastitis.

12 It has been well established that the infusion of
13 antibiotics into the mammary gland at a time when the cow
14 will not be milked for 60 days enhances udder health and
15 promotes the production of higher quality milk in the
16 subsequent lactation. The high risk period found at the end
17 of the dry period, on the other hand, is more appropriately
18 mediated by the use of vaccinations, where appropriate,
19 housing and environmental upgrades and nutritional programs
20 directed toward maximizing the performance of the immune
21 system.

22 (Slide.)

23 DR. RIDDELL: Very young calves, two to 10 days of
24 age, may encounter chance overwhelming systemic bacterial
25 infections, typically with Gram negative organisms. The only

1 treatment which will enable this young class of animal to
2 overcome the bacterial infection found within the blood
3 stream will be systemic antibiotics specific to the suspected
4 organisms.

5 (Slide.)

6 DR. RIDDELL: The practice of feeding
7 antimicrobials, such as the ionophores, which alter ruminant
8 flora populations, to enhance preferential development of --
9 production of volatile fatty acids to promote efficiency.
10 Bambermycins, tylosin, virginiamycin and tetracyclines
11 enhance growth promotion, enhance feed efficiency and work
12 towards disease prevention, resulting in improved animal
13 performance, productivity and efficiency.

14 There are numerous label indications for
15 antibiotics in the feed. These include increased rate of
16 gain, improved feed efficiency, the prevention or liver
17 abscesses and the control and treatment of anaplasmosis.

18 The prevention of liver abscesses and the control
19 of anaplasmosis directly impact animal health and well being.

20 Other methods of control of these two conditions are limited
21 or non-existent. The well proven decades old vaccine for
22 anaplasmosis has been off of the market for several years.

23 The use of fed antimicrobials to enhance rate of
24 gain and feed efficiency results in more efficient animal
25 protein production, more effective use of feed grains and

1 more responsible nutrient utilization in terms of waste
2 management.

3 (Slide.)

4 DR. RIDDELL: As I mentioned in the beginning, it
5 is very difficult to define, in the limited time available,
6 all potential uses of antibiotics in ruminants. Hopefully, I
7 have stimulated some thought and provided some framework for
8 discussion by some of the representative examples I
9 presented, and hopefully, discussion over the next three days
10 will help further explore these uses and answer questions
11 pertaining to this topic.

12 In summary, antibiotic use in ruminants is
13 necessitated when the variables involved in animal
14 agriculture, such as environmental conditions, chance
15 exposure to infectious agents and variations in individual
16 animal susceptibility predispose to individual animal disease
17 or outbreaks in herd populations. The proper evaluation,
18 thorough diagnostic procedures and the implementation of
19 appropriate therapies, particularly under the auspices of a
20 valid veterinary client patient relationship, when
21 appropriate, will enhance the efficacy and safety of the use
22 of antibiotics in ruminants. Thank you.

23 (Applause.)

24 CHAIRWOMAN LATHERS: I think we have time for one
25 question, if someone would like to ask a question.

1 (No response.)

2 CHAIRWOMAN LATHERS: Our next speaker will be
3 Dr. Dennis Wages. Dennis is currently a professor of poultry
4 health management at the College of Veterinary Medicine at
5 North Carolina State University. Dennis earned a bachelor of
6 science in poultry science at the University of Arkansas, a
7 doctorate of veterinary medicine at Kansas State University,
8 completed a pathology residency at Iowa State University and
9 is currently at diplomat status with the American College of
10 Poultry Veterinarians. Dr. Wages.

11 **ANTIBIOTIC USE IN POULTRY - AN OVERVIEW**

12 **By Dr. Dennis Wages**

13 DR. WAGES: Thank you, Dr. Lathers. Good morning.

14 I have been asked to give an overview of antibiotic use in
15 poultry, probably one of the areas of most controversy in the
16 use of antibiotics in food animals, and hopefully, I can give
17 you an idea of why we do what we do and some of the thinking
18 that is involved in the utilization of antibiotics.

19 I will touch base on therapeutics in the water,
20 therapeutic feed grade antibiotics, growth promotion and the
21 use of injectables in the limited time that I have.

22 (Slide.)

23 DR. WAGES: Antibiotic use in the poultry industry
24 has been a fundamental intervention strategy since the 1960s.
25 Even though preventative disease management is the primary

1 focus of the industry's disease control, and we maintain much
2 emphasis on vaccination protocols and the study of
3 immunology, disease outbreaks that do occur, and it is a fact
4 of life that it requires antibiotic therapy in some cases.

5 The majority of antibiotic treatment in poultry for
6 acute disease outbreaks occurs via the water route. When a
7 disease is identified within a flock, morbidity and mortality
8 are assessed, necropsies are performed and a diagnostic
9 evaluation is initiated in the diseased flock.

10 When culture and antibiotic susceptibility
11 profiling has been performed, the veterinarian considers farm
12 history, previous diagnostic evaluations specific to that
13 farm and in that area and initiates appropriate control
14 measures, which does include environmental and management
15 changes, as well as, in some cases, the use of antibiotics.

16 We currently have eight classes of antibiotics used
17 for water administration, and they represent 15 antibiotics
18 that are approved for use for the treatment of acute
19 bacterial diseases in poultry. They are dosed based on
20 milligrams per kilogram of body weight -- that is, the pounds
21 of meat in the house -- at labeled indications or based on
22 the veterinarian's clinical judgment.

23 Any use of antibiotics not in accordance with the
24 label indications are to be done within the guidelines
25 outlined by AMDUCA. The antibiotics commonly chosen for use

1 in appropriate disease outbreaks as intervention tools for
2 water administration include the tetracyclines, streptomycin,
3 neomycin, bacitracin and penicillin. These antibiotics
4 represent tools that we use. We don't treat a lot. But when
5 we do, these are the ones that are used more commonly.

6 Antibiotics that are less routinely or commonly
7 chosen include lincomycin, streptomycin, tylosin,
8 erythromycin and sulfonamides. These antibiotics are used.
9 The latter group are used in the industry; however, they are
10 used to treat diseases that we don't say on a day-to-day
11 basis. You could take probably eight percent of our
12 treatment for acute outbreaks and lump them into E. coli
13 bacillosis and falcollera (sic) in turkeys and chickens, and
14 that is the majority of what we treat for.

15 (Slide.)

16 DR. WAGES: The fluoroquinolones are used at
17 labeled indications. They are not used in any extra label
18 format, in that it is against federal law to do so, and they
19 are used sparingly in our industry. They are cost
20 prohibitive. It is not uncommon to put \$1,500 into a flock
21 of chickens with the use of the fluoroquinolones, and it is
22 just not cost effective to utilize such treatments when you
23 look at a cost per pound benefit. It is a very important
24 drug to our industry.

25 (Slide.)

1 DR. WAGES: A survey of the National Chicken
2 Council places fluoroquinolone use somewhere between one and
3 two percent in the broiler production. We try to hold it in
4 reserve. The fluoroquinolones currently represent the only
5 drugs consistently effective for coli bacillosis in turkeys
6 and chickens, and that is our number one disease.

7 Because of the economic impact of disease in
8 poultry, disease prevention through rigid vaccination
9 protocols and management improvements are emphasized while
10 veterinarians in integrated companies closely regulate
11 treatments. No, we are not perfect. Companies that have
12 used antibiotics excessively and inappropriately instead of
13 utilizing stringent disease prevention programs are simply no
14 longer in the poultry business. They can't afford to be.

15 The aforementioned antibiotic intervention tools
16 are used in specific diseased flocks regarding specifically
17 diagnosed bacterial infections, and we do not use antibiotics
18 in healthy flocks. However, in a house of 25,000, when a
19 disease such as coli bacillosis occurs and we are losing five
20 to seven birds per thousand, we do have a number of birds
21 that we call at-risk that are not diseased and appropriate
22 antibiotics are used in the diseased house. But, in fact,
23 there are birds that aren't sick at that time in a
24 prophylaxis use of antibiotics. Long-term therapy for
25 chronic infection is not cost effective, nor is it performed

1 in the poultry industry.

2 (Slide.)

3 DR. WAGES: Growth promoting antibiotics are added
4 to the feed primarily as a control measures for common
5 enteric bacterial diseases, specifically clostridial
6 infection that result in necrotic enteritis. History has
7 determined growth promoting antibiotics and their use to be
8 sub therapeutic, a term that has been used against the
9 poultry industry and the food animal industry for years and a
10 term that I personally feel is inappropriate, and I will try
11 to explain.

12 If one looks at the definition of therapy and
13 treatment, there is, under all the definitions in Dorland's
14 Medical Dictionary, areas where prophylaxis and prevention
15 are identified as tools in the treatment and initiation of
16 therapy. The reason sub therapeutic was adopted years ago to
17 describe growth promotion can be explained in my mind.

18 In poultry, sub-clinical infections with coccidia
19 in commercially raised flocks predispose birds to necrotic
20 enteritis. Even though the anti-coccidial feed additives are
21 routinely and were routinely used in commercial poultry,
22 antibiotics such as virginiamycin, bacitracin and lincomycin
23 were added to the feed to prevent necrotic enteritis
24 infections due to *Clostridium perfringes*.

25 These antibiotics were needed because the coccidia

1 preventative feed additive to control coccidiosis were static
2 and not cidal, thus preventing clinical coccidiosis in the
3 flock, but not preventing sub clinical infections and the
4 protozoa proliferation within the intestines that predisposed
5 the bird to necrotic enteritis infections.

6 Since the levels used in the feed of these
7 antibiotics to prevent and control necrotic enteritis were
8 lower than those used to treat active, acute outbreak of
9 enteric they were coined sub therapeutic; below the
10 therapeutic dose needed to treat an active infection. Even
11 though we did control infection. A perfect example is 50
12 grams per ton of an antibiotic would control necrotic
13 enteritis. If they broke with the disease, it would take 400
14 grams per tone to treat an active infection within a five to
15 seven-day period.

16 I don't think in today's terminology sub
17 therapeutic is appropriate, although it is very coined and
18 people are very comfortable with it. Today, we still use
19 virginiamycin, bacitracin, lincomycin and bambarmycin to
20 prevent and control necrotic enteritis and for growth
21 promotion; however, since the 1980s -- in fact, about 1982 --
22 the poultry industry has not used the tetracyclines,
23 penicillin, sulfonamides or erythromycin in feed for growth
24 promotion or at low levels for disease control.

25 (Slide.)

1 DR. WAGES: Besides disease control, antibiotics
2 have other modes of growth promotion, some known and many
3 unknown. Certain antibiotics used in poultry increase
4 chilled and hot carcass weight, improve breast yield and have
5 protein sparing effects in the intestines. Many of these
6 growth promoting mechanisms and results can be attributed
7 mainly to control of sub clinical disease, such as necrotic
8 enteritis, and some mechanisms specifically are unknown.

9 Some growth promoting antibiotics increase
10 intestinal tensile strength, the strength of the intestine.
11 This intestinal health and tinsel strength is important not
12 only for the overall health of the bird, but also as an
13 advantage at the time of processing to prevent bacterial
14 contamination.

15 It has been demonstrated that certain antibiotics
16 increase tinsel strength and intestinal integrity that
17 prevents the tearing of intestines during the automated
18 evisceration process. This helps prevent contamination from
19 intestinal breaking at processing, which decreases the
20 bacterial load at processing on our carcasses.

21 (Slide.)

22 DR. WAGES: Besides overall disease reduction and
23 other cost benefits, growth promotion increases feed
24 utilization by decreasing the amount of feed required to
25 produce one pound of gain. To put this in perspective, if

1 feeding an antibiotic to control necrotic enteritis or to
2 improve growth promotion and feed efficiency would increase
3 the efficiency 0.01 or 100th of one pound, which would reduce
4 feed conversion from a 2.00 to 1.99. This represents a
5 savings to our industry in the feed utilization of 375
6 million pounds.

7 This reduces the amount of grain required to
8 furnish this feed, reduces electricity and the milling, or to
9 mill this feed, reduces gasoline to deliver this feed. It is
10 a snowball and domino effect on reducing the cost for a
11 chicken.

12 Enhanced feed utilization also reduces fecal
13 nitrogen and phosphorous excretion in litter, thus is an
14 environmental advantage when applying litter to pastures and
15 crops, another point that is of concern in intensive
16 livestock grazing areas.

17 Growth promoting antibiotics or any other use of
18 antibiotics are not used to treat poor management.
19 Antibiotics simply do not replace deficiencies in management,
20 despite popular press.

21 (Slide.)

22 DR. WAGES: Antibiotics added to the feed are
23 rarely used to treat acute disease outbreaks. Now, this is
24 feed grain antibiotics for acute outbreaks of disease.
25 Antibiotics that are approved for use in this manner include

1 the tetracyclines, erythromycin, bacitracin, tylosin and
2 sulfonamides. And all of my list of antibiotics may not be
3 entirely complete, but I think they are the ones that are the
4 most common.

5 These products are difficult to use in the
6 treatment of an acute outbreak routinely. It requires the
7 removal of coccidiostat from the feed or requires a cross
8 clearance with the commonly used coccidiostat during
9 treatment, and either removing the coccidiostat or trying to
10 find cross clearances and have companies put their money into
11 cross clearances, none are very palatable to the industry at
12 this time.

13 There are cases, such as chronic fowl cholera in
14 breeders and some Mycoplasma species infections where pp.
15 infections where feeding a feed grade antibiotic at a
16 therapeutic intervention level for 10 to 14 days may be cost
17 effective and potentially reduce condemnations at processing,
18 but this procedures is rare.

19 (Slide.)

20 DR. WAGES: Injectables. There are antibiotics
21 approved for use as injections in day old chickens and
22 turkeys to control omphalitis or yolk sac infections. This
23 procedure has been performed for over 30 years in the poultry
24 industry.

25 Now, in the incubation process, at approximately 19

1 and 27 days of age, in chicks and poults respectfully is
2 taken from the outside of the chick or poult and drawn into
3 the body cavity. This period of time is a window of
4 opportunity for bacteria to enter the developing embryo.

5 Until 1993, yolk sac infections in chickens were
6 controlled with the injections of antibiotics such as
7 gentamicin and spectinomycin at 1 day of age. In 1993, with
8 the approval of Marek's disease in ovo vaccination, which
9 basically vaccinates for Marek's from the time that chickens
10 are transferred from the setting incubators to the hatching
11 incubators. This process was approved.

12 This in ovo technique also provided a window of
13 opportunity for an injection of antibiotic at the time of
14 vaccination for Marek's that would try to and at least
15 potentially more effectively control the yolk sac infection
16 by placing the antibiotic at the point of contamination when
17 the yolk sac is withdrawn into the body cavity.

18 If the bacterial contamination occurred at any
19 point during the egg collection, storage and incubation of
20 the eggs in ovo antibiotics, in our mind, felt like there was
21 a benefit to the chick in controlling bacterial yolk sac
22 infections.

23 Now, the only antibiotic approved for such
24 injection is sarafloxacin, a fluoroquinolone. And I will
25 tell you that it is not and has not -- and we kind of snubbed

1 sarafloxacin. We do not use it in day old in ovo injection,
2 nor in any other procedures of injections in poultry.
3 Sarafloxacin injectable, in the poultry industry's mind, is
4 predominantly a dead issue.

5 The poultry industry felt that fluoroquinolones
6 were too important to be used as a day old preventative or
7 control for yolk sac infection or omphalitis.

8 The two most commonly used antibiotics for in ovo
9 administration are ceftiofur and gentamicin. These are not
10 approved for in ovo administration. They are used under
11 AMDUCA as extra labeled.

12 Although stringent cleaning and disinfecting of
13 hatcheries and hatchery equipment are performed daily, these
14 procedures cannot prevent some bacterial contamination from
15 the egg collection and storage process. The use of
16 antibiotics in chicks and poults and/or in the developing
17 embryo provide the poultry veterinarian a useful tool for
18 controlling yolk sac infections in chicks and poults during
19 the first week of life.

20 (Slide.)

21 DR. WAGES: Antibiotic intervention in poultry is a
22 tool. It is one tool in a total disease prevention program
23 that emphasizes preventative disease management and
24 vaccination protocols, et cetera. We simply can't afford to
25 have disease in poultry flocks and maintain our current cost

1 per pound benefit of production.

2 Our industry does not encourage nor endorse
3 indiscriminate use or excessive use of antibiotics in our
4 flocks. Currently, the American Association of Avian
5 Pathologists Committee on Drugs and Therapeutics, which I am
6 currently the chair, are drafting specific guidelines to
7 promote judicious use of antimicrobials in poultry to
8 preserve the efficacy of all antimicrobials in both poultry
9 and human medicine.

10 And I assure you we are looking at all ways that we
11 use antibiotics and determine whether we are doing things in
12 the most effective way and what impact we have. We are
13 convinced that what we do in poultry medicine and in our food
14 animal species regarding poultry no longer just impacts the
15 poultry and the growers and the companies. The impacts are
16 global.

17 This effort supported by the American Veterinary
18 Medical Association and the AVMA Committee on Judicious
19 Therapeutic Antimicrobial Use. This will provide the front
20 line poultry veterinarian in poultry to continue to make
21 informed decisions regarding poultry intervention strategies.

22 Our antibiotic arsenal is small, but when the need for
23 antibiotic use is warranted, we need to have access an
24 appropriate therapeutic avenue.

25 This overview is kind of short. Hopefully sweet

1 and to the point. It doesn't, I am sure, answer all the
2 questions. I hope that it at least does explain some
3 mechanism and things that we do; why we do. I am sure it
4 won't satisfy everyone, but if there are any questions, I
5 would be happy to take them now. Thank you very much.

6 (Applause.)

7 CHAIRWOMAN LATHERS: Are there any questions for
8 Dr. Wages?

9 (No response.)

10 CHAIRWOMAN LATHERS: If not, thank you very much.

11 DR. WAGES: Thank you.

12 CHAIRWOMAN LATHERS: The next speaker is Dr. Robert
13 Morrison. Bob is an associate professor at the College of
14 Veterinary Medicine at the University of Minnesota. He is
15 director of Pig Champ, a software business serving the swine
16 industry, he is a co-owner of a 2,000 sow multiplication
17 herd, he is a board member of Allison Meats, a regional meat
18 produced and processor, he is vice president of the American
19 Association of Swine Practitioners, and, as such, he works
20 closely with veterinarians and has a broad experience which
21 combines both applied science and business aspects in terms
22 of pork production.

23 You will now hear his presentation on antibiotic
24 use in swine. Dr. Morrison.

25

ANTIBIOTIC USE IN SWINE - AN OVERVIEW

By Dr. Robert Morrison

DR. MORRISON: Thanks very much. I am going to just give an overview of how veterinarians approach the treatment decision within swine facilities, and I would like to thank the committee for asking the American Association of Swine Practitioners to be here.

(Slide.)

DR. MORRISON: What I was led to believe at least is that many of you here maybe weren't all that familiar with pork production, and so I put this slide in just to show you a representative barn. Not, of course, a barn that all pigs go through like this, but not an atypical barn that a lot of pigs might go through in terms of their growth process.

And so what you can see here is a barn that might have 1,000 or 1,200 pigs in it, and they would be all relatively similar in age and weight. They probably came from one sow barn, and they came into this facility let's say around eight or nine weeks of age and they are going to stay here for three and a half months or so, at which time the barn -- again, if this was an example barn -- would be emptied and all of these pigs would go to market.

The barn would be completely washed down with a power wash and hot water disinfectant, and basically, the next group of pigs that would come in would come into the

1 equivalent of a new basically disease-free, if you think of
2 that way, barn. And that sort of production is what we try
3 to produce pigs through in a way today so the new group that
4 comes in has a new chance to do well.

5 So that is not an atypical barn, as I said. That
6 would be called a naturally ventilated barn. So you have got
7 curtains on the side, and you can see the curtain on the left
8 side there is open, letting light in. On a hot summer day
9 the curtain on both sides will be open, and you will get nice
10 ventilation going through.

11 Now, what you can also see there is that those pigs
12 have plenty of opportunity for touching each other; nose to
13 nose contact, oral fecal contact, and so there is quite a bit
14 of opportunity for transmission of infectious agents. And
15 so, when something gets in there, it is very likely to spread
16 if you don't have sort of the set up right to try and do
17 things right.

18 (Slide.)

19 DR. MORRISON: Now, if you think of that barn, I
20 would like you to just ask yourself which of these three is
21 it most similar to. Is it most similar to a daycare facility
22 or a residence at a small liberal arts college or a nursing
23 home? And you could argue which one it is most similar, but
24 what I am going to propose today is that it is most similar
25 to a residence where you have got a group of relatively --

1 let's say mature individuals, hopefully mature, coming and
2 they are going to stay there for a while.

3 And they are not going to come in and go, like in a
4 daycare where you are going to go home, bringing new
5 infectious agents back every day. Anybody who has got kids
6 at daycare you know you are sick virtually every other day.

7 In a residence, however, you are going to come and
8 you are going to stay and you are going to stay there for
9 eight months and then you are all going to go home and the
10 residence is emptied. The other important part about that
11 residence versus the other two is that they are
12 immunologically mature.

13 They are not like a daycare facility where babies
14 don't have a well developed immune system let's say or not
15 well exposed. They are not like a nursing home where you
16 have got perhaps immune compromised individuals, people who
17 cannot withstand infection. These pigs in this barn are
18 physiologically and immunologically mature, and they are
19 going to stay there. They are going to respond well to
20 vaccines, et cetera.

21 I say there at the bottom, "We must consider the
22 population when treating a disease." We have those 1,000
23 pigs in there and maybe three of them today are sick, but 997
24 are at risk. So that is very important to us when we think
25 about the treatment decision for a barn.

1 When I am teaching veterinary students, I will have
2 70 students in the class let's say. And on a bad day in
3 February, 10 will be absent from flu virus, 15 should be
4 absent because they are, you know, sniffing, they are
5 dripping, they are shedding quantities of virus into the air
6 that infect the professor, 15 of them are probably feeling
7 kind of rotten and the other 30 are pretty good.

8 That is the same situation when we have that barn
9 with 1,000 pigs in it. If you have something break with it
10 today, a few are going to die. Some are going to be quite
11 clinically sick, and we want to, hopefully, turn those
12 around. Maybe half of them are at risk of getting sick, and
13 maybe 30 percent of them are going to do absolutely fine.

14 (Slide.)

15 DR. MORRISON: So, when we treat or not, a
16 veterinarian, intuitively, is going to go through these sort
17 of decisions. What this particular disease costs in that
18 1,000 pig barn. What that disease costs. If it costs
19 nothing, I am very likely not going to do anything.

20 The impact on the pigs' well being of that
21 particular disease; how does it affect their well being. So
22 we may have some diseases that maybe don't have a huge cost,
23 but they may affect the well being of some individuals, and
24 we may decide to treat on that.

25 What will likely happen if I ignore it? Will it go

1 away? You know, the vast majority of infections that take
2 place just go away on their own. And fortunately, for
3 veterinarians we ride the descending curve, if you remember
4 your veterinary school of animals and individuals getting
5 better. Some will stay the same or some will get worse.

6 The cost of the proposed management changes in
7 treatment. That is one of the things we are going to always
8 weigh. What is this going to cost, the scenario that I am
9 treating, versus what is it going to cost for my
10 recommendation. And hopefully, my recommendation saves
11 money. And the likelihood of resolving the problem with
12 these changes in treatment. So, some probability of success.

13 And by the way, all of these slides are going to be
14 available, I think, to all of you. So you don't need to copy
15 this down.

16 So, those are the intuitive decisions that
17 veterinarians go through when he or she is going to recommend
18 treatment. Now, some folks have put these into very
19 elaborate spreadsheets, and they are very nice tools for
20 deciding whether to treat or not.

21 (Slide.)

22 DR. MORRISON: We diagnose a problem by the
23 following: We are going to look at records. More and more
24 today pig production is based on very elaborate and detailed
25 record systems, and so we are going to look at records. We

1 may have feed consumption, water consumption, weight gain
2 curves, as well as mortality. Maybe we have a coughing
3 index. Somebody goes in and measures coughing. So we have
4 got a lot of records to try to figure out what is going on in
5 that barn of 1,000 pigs.

6 We will have clinical signs obviously in history.
7 We have got veterinarians who are trained for many years to
8 figure out what is this picture telling me. We will have
9 serology done both on cross sections in some cases and serial
10 bleeding. In other words, we will bleed pigs over time to
11 figure out are they sero converting to agent "x."

12 And then we will have postmortem on both pigs that
13 die, and sometimes we will sacrifice representative pigs and
14 try to figure out what is happening in the population here.
15 And we will have some pigs that we will sacrifice and do a
16 postmortem in order to figure out what is going on in the
17 other 999.

18 (Slide.)

19 DR. MORRISON: Now, despite that sort of elaborate
20 protocol that we will have to try and figure out what is
21 going on, we have some systems that -- like here is a farm
22 that has a problem, and you can see each dot there is a group
23 of 1,000 pigs. And the "xx" that is down at the bottom is
24 time. And the "y" axis, by the way, is mortality.

25 So assume for the moment that every dot is 1,000

1 pigs, and you can see that way back in '96 they had roughly,
2 you know, one percent. Down at the bottom left you can see
3 we are down around one percent, two percent mortality. And
4 over time, what you see here is that this mortality is going
5 up, and, of course, that is very disconcerting to the owners,
6 very disconcerting to the veterinarians -- their jobs are on
7 the line -- and they are spending a lot of money to try to
8 figure this out to make this curve go down.

9 But this is a very frustrating case. You can also
10 note, for those of you who are unfamiliar with finishing, we
11 like to have mortality down two percent or lower. You are
12 always going to have a few die that just -- whatever. But we
13 like to have it down in this one, two percent range. That is
14 a nice, well run barn.

15 But when you are getting up here in this five, six,
16 seven percent, you can see that this is also very
17 unpredictable. This is just a nightmare for these folks to
18 try and figure out what is going on and how to fix it.

19 (Slide.)

20 DR. MORRISON: In that graph what I was showing you
21 was mortality, and something that we teach and emphasize a
22 lot is that mortality is probably just the tip of the iceberg
23 and underneath that. So we said we will tolerate one, two
24 percent mortality. When you get up three, four, five percent
25 mortality, what you have got is a lot of pigs that are going

1 to become sick and need to be culled. Or at least they are
2 going to go to market light than what we would like. Okay?
3 And that is a loss.

4 And then, furthermore, you have got pigs that are
5 growing slower. This top group there, some of those will go
6 to different market, like a light market in town where they
7 consume pigs that are much lighter than most of those. The
8 greater majority of those are going to go to market light,
9 and they are going to cost me an enormous amount of money.
10 So mortality is just the tip of that iceberg when it comes to
11 cost of the producer.

12 And so, I have got my barn of 1,000 pigs and let's
13 say only four percent are going to die, and I say only in
14 quotation marks. But 96 percent of them are affected, and so
15 that is very, very important when I make my treatment
16 decision.

17 (Slide.)

18 DR. MORRISON: An important point for me is that
19 treatment is a short-term expense. Every time I add a
20 treatment, it costs money. It takes money off the bottom
21 line. So I don't want to treat any more than I need to, but
22 you weigh that against management change. If I can go in and
23 take that last graph where that line was going up, every
24 group of pigs there is probably going to require some sort of
25 treatment. That is an expense.

1 Now, I am going to weigh what can I do in that
2 system or that barn as an investment to try to change that,
3 to try to turn that curve around. So management is going to
4 be viewed as a long-term investment, and I am going to look
5 for some return on the investment.

6 And you can see here that we might look for changes
7 in housing, we might change the way by which pigs flow, we
8 might change the health of the incoming stock and lastly, at
9 the bottom, we might change feed and water supply. All of
10 those are going to cost, depending on the size of the farm,
11 hundreds of thousands, perhaps tens of thousands; perhaps
12 millions of dollars.

13 I will give you an example, a recent example
14 looking at some numbers from a farm system. They have looked
15 at groups that go through barns that have natural
16 ventilation. So the curtains are open; nice summer breeze
17 coming through. They have looked at those versus groups that
18 go through with mechanically ventilated barns. So you have
19 got fans exhausting air and controlled inlets letting the air
20 in.

21 They have determined that in the groups that have
22 the mechanically ventilated barn they have roughly about .8
23 percent lower mortality than the groups that go through with
24 curtain ventilated barns, and they said, well, we have to
25 look.

1 If we have curtain sided barns, we know that we are
2 going to have higher mortality, we are going to have poor
3 feed efficiency, we are going to have lower gain, we are
4 going to have more expense for treatment, so let's ante up.
5 And they are actually spending -- I think it is \$20,000 per
6 barn to change it over to a mechanically ventilated barn so
7 that they can reduce the cost and they can improve the
8 performance on every group that goes through there.

9 So that is a management change that they will try
10 and impose across all barns, such that they reduce the
11 treatment expense.

12 (Slide.)

13 DR. MORRISON: The treatment program is selected
14 based on these following criteria: And Dennis gave you a
15 nice summary of actual treatment that the poultry business
16 uses. I am not going to go through drugs, but they all will
17 follow this sort of a regime.

18 What is my diagnosis? And it is a best guess.
19 Hopefully, it is an educated best guess. Hopefully, it is
20 right. But what is my presumptive diagnosis? What do I know
21 about this herd historically? What is the prevalence and
22 incidence of this disease? Do I need to treat at all? Is it
23 just one pig in the 1,000? And the incidence. How many new
24 pigs are getting sick every day?

25 Will the owner do or will the staff do what I ask

1 them to do? A common cut off let's say is in the 10 or 20
2 percent range of infected pigs or affected pigs that need
3 treatment. If more than 20 percent are infected and
4 affected, I probably am not going to get that owner or staff
5 person to go in and inject pigs. It is just too big a task.

6 And so, if I say, listen, it is really cheap if you
7 will just go in and inject these 250 pigs once a day for
8 three days or twice a day for three days, forget it. You
9 know, the staff person who is getting \$8.00 an hour isn't
10 going to do it.

11 So I may have to go in and water medicate. Or, in
12 some cases, as we will see, I may have to go in and feed
13 medicate, because I can't get them to do what I think they
14 ought to do, from a compliance point of view.

15 Benefit costs of treatment options. I am going to
16 think about that. I am going to look at my lab results. I
17 am going to weigh, obviously, my clinical experience and the
18 antibiotic options available. All of those are the criteria
19 that I am going to consider.

20 (Slide.)

21 DR. MORRISON: Now, I just want to -- there is a
22 very detailed treatment set of guidelines that the veterinary
23 employs when choosing a treatment. I just want to go over
24 these very quickly.

25 (Slide.)

1 DR. MORRISON: First, the veterinarian is going to
2 decide, well, am I going to inject or water medicate? Am I
3 going to use a food animal drug or, in some cases, in the
4 rare case, a non-food animal drug? Am I going to use it
5 according to label or so-called extra label? If I go in with
6 an injection or a water medication, am I going to follow up
7 with feed medication or am I just going to stop? And lastly,
8 if I do switch to a feed medication, when am I going to stop
9 medication. So that is the steps that a veterinarian will go
10 through.

11 (Slide.)

12 DR. MORRISON: Just very quickly, the first
13 decision. Well, is it three pigs out of 1,000 or is it 250?
14 So, if it is 250, I am probably going to have to go in and
15 water medicate because I won't get very good compliance on
16 injection.

17 (Slide.)

18 DR. MORRISON: The route of choice is always going
19 to be to choose a drug labeled for food animals that contains
20 the proper ingredient. It is always going to be your first
21 choice.

22 (Slide.)

23 DR. MORRISON: And then you are going to -- if you
24 have got this drug in the proper dosage form, as labeled for
25 the indication, and I believe it is clinically effective, I

1 am going to use it according to label.

2 (Slide.)

3 DR. MORRISON: If not, if not in the proper dosage
4 form, it is not labeled for indication and I don't think it
5 is clinically effective, I go to extra label. Where I
6 require these criteria I have got to have a veterinary/client
7 relationship. I have got to know these pigs. In a way, I
8 have got to be personally responsible and I have got to be
9 available.

10 I have got to sufficient scientific information to
11 insure an adequate withdraw, I have got to be able to
12 preserve animal or group ID and I have got to have records
13 and labels.

14 (Slide.)

15 DR. MORRISON: In the rare case where we can't go
16 this route, we are going to use a non-food animal drug where
17 it is not prohibited, and again, very importantly, where I
18 have got enough evidence to give a valid withdraw time.

19 (Slide.)

20 DR. MORRISON: Dennis covered this briefly. When
21 do we medicate in the feed? Well, why would we? We would
22 because it gives us the broadest coverage of the population
23 at risk. I can medicate them all very easily. It is very
24 labor efficient, it is very simple and it may be the cheapest
25 program.

1 But why don't we always just go in and medicate
2 with feed then? Well, it is probably somewhat difficult to
3 achieve therapeutic levels in sick pigs. Sick people don't
4 eat, sick pigs don't eat, and so they are not going to get
5 the medication that we want them to get.

6 There is the potential for contamination of other
7 feeds. Some pigs that are not sick will receive the
8 medication. We don't want that. They are at risk, but it is
9 kind of a waste, unless they are going to get sick without
10 it.

11 And in some cases, just as it may be the cheapest
12 program, it may be the most expensive program. So you are
13 always, as a veterinarian, going to be weighing this. What
14 is my treatment program?

15 (Slide.)

16 DR. MORRISON: I did a brief -- just a little
17 survey in preparation for this meeting, and I asked some
18 veterinarians, and I was quite impressed with their awareness
19 and compliance with the guidelines. Some of these
20 veterinarians have very detailed treatment protocols for
21 clients.

22 They told me that they choose their product
23 selection based on effectiveness first and cost second. And
24 remember, this effectiveness is going to be their clinical
25 perception in many cases and based on historical experience.

1 For some of them I saw some very elaborate spreadsheets for
2 comparing drug costs and routes of delivery.

3 Generally, they will go between 10 and 20 percent
4 as their cut off for whether they are going to go for
5 injection versus water. Feed medication was generally used
6 for chronic or preventive situations. And lastly, I saw a
7 nice spreadsheet for cost effectiveness of growth promotants.

8 (Slide.)

9 DR. MORRISON: The last slide. I think it is
10 important to recognize that within our industry I showed you
11 an example of a 1,000 pig barn. We could go and I could take
12 you to some barns that are not, in my view, well run. And I
13 could take you to some other barns that are incredibly well
14 run.

15 And so, in our industry I think of health
16 management as being on a continuum, and you have got some
17 farms out here that don't have good health and you have got
18 some farms out here that have extremely high health. And
19 when you look at sort of the descriptors of a low health
20 system or a low health farm, you will find that -- this is
21 probably more detail than you need, but they will have
22 multiple sow sources feeding in. So it is just like that
23 daycare facility.

24 If you have got 50 kids in a daycare, they are
25 going home every day to 50 different homes and bringing back

1 200 bugs the next day. Okay? So multiple sources just
2 creates a wonderful environment for disease to transmit
3 versus one source.

4 Again, I won't go through any details, but all of
5 these are descriptors of a poorly run management system. And
6 you come over here and all of these are nice. We know, from
7 experience, that those are going to be well run barns if they
8 can do these sorts of things.

9 (Slide.)

10 DR. MORRISON: Now, if you could look at the whole
11 industry out there, you can imagine that there is going to be
12 sort of a bell shaped curve or normal distribution of health,
13 and the majority of them are going to be somewhere in the
14 middle. And we will have a few out here that are really well
15 run, and we will have a few out here that are really poorly
16 run, and these are the ones that are real challenges.

17 (Slide.)

18 DR. MORRISON: The challenge for us as
19 veterinarians -- this is a fancy graphic now -- is to take
20 this and move this curve in the right direction. So it is a
21 continuum. It is important to recognize that health
22 management out there is a continuum. We, as veterinarians,
23 are trying to move everybody over to the right, and it is all
24 sort of process that we are moving in.

25 And I am very confident. If I look back where we

1 were 15 years ago -- I was in practice at the time -- I would
2 liken a lot of those farms over there to low health farms.
3 And I look at where what we work with today, and a lot of
4 them are moving well over here. It is incredible.

5 And if I look 15 years from now, I am quite certain
6 that we are going to be over here on this side of the graph
7 as we continue to move farms off to the right.

8 (Slide.)

9 DR. MORRISON: I would just like to acknowledge
10 that I did do this survey, and I appreciate the participation
11 of these veterinarians who I contacted. I also used the AVMA
12 brochure. And also, the AASP has a pharmaceutical issues
13 task force that I am a part of, and I appreciate my
14 participation in that group, Tom. Thanks very much for your
15 attention.

16 (Applause.)

17 CHAIRWOMAN LATHERS: Thank you, Dr. Morrison. Are
18 there any questions for Bob?

19 (No response.)

20 CHAIRWOMAN LATHERS: If not, we will now move on to
21 our next discussion of antibiotic use in aquaculture,
22 presented by Randy MacMillan. Dr. MacMillan is vice
23 president of research and environmental affairs at Clear
24 Springs Food, where he is responsible for the research and
25 development program environment, stewardship and quality

1 assurance.

2 He is the president of the National Aquaculture
3 Association and the past president of the U.S. Trout Farmers
4 Association. He is also the past president of the Idaho
5 Aquaculture Association and the past president of the
6 American Fisheries Society for Fish Health Session. He is
7 the current chair of Minor Use/Minor Species Coalition. So,
8 with that, we will now have a discussion of antibiotic use in
9 aquaculture. Randy.

10 **ANTIBIOTIC USE IN AQUACULTURE - AN OVERVIEW**

11 **By Dr. Randy MacMillan**

12 DR. MacMILLAN: We are having to reboot. I am not
13 promoting Microsoft. It just happens to be what is on this
14 computer.

15 (Pause.)

16 DR. MacMILLAN: I represent a minor animal species
17 group, and we don't have the kinds of resources that other
18 sorts of people have, other sorts of animal industries have.
19 When you think about minor animal species, it is important
20 to understand why they are minor animal species. It is
21 because not many of those animals are eaten.

22 And in aquaculture, which has been around for 300
23 or so years in the world, it is a very young industry in the
24 United States.

25 (Pause.)

1 DR. MacMILLAN: So what I will do is go ahead and
2 shut this down completely, and I will go ahead and start.

3 CHAIRWOMAN LATHERS: Please do.

4 DR. MacMILLAN: And then we will go quickly through
5 some of these slides, once this boots up properly.

6 I think one of the big questions before this group
7 is to what extent the antibiotics currently used or
8 potentially used in U.S. aquaculture, and I really want to
9 emphasize United States aquaculture and emphasize that
10 throughout this presentation.

11 But, to what extent the antibiotics or potentially
12 used in U.S. aquaculture contribute to increased morbidity or
13 mortality, resulting from a reduction in the efficacy of a
14 specific antimicrobial therapy of human disease as a
15 consequence of antibiotic resistance by the bacterium
16 involved in the disease process. And I have a slide that
17 shows this.

18 But as I understand the purpose of this workshop or
19 the task before us, it is to identify, with objective
20 methods, how we are going to quantitate the risk. And I can
21 tell you in United States aquaculture this is going to be a
22 very formidable task, because there is considerable evidence,
23 United States evidence, that the risk is so very low, in
24 spite of some of the rhetoric that has gone on before us,
25 before me anyway, about how dangerous aquaculture is.

1 Unfortunately, what has happened is people who have
2 made those claims, those statements, are using aquaculture
3 practices that are practiced in third world countries that
4 actually dump human sewage and homothermic animal waste into
5 those aquaculture facilities as a way to fertilize those
6 facilities; to provide nutrients for algae that provide food
7 for zooplankton that then provide food perhaps for the fish.

8 In the United States, that doesn't happen at all,
9 and so, we have really gotten off the realistic track of what
10 happens in U.S. aquaculture.

11 (Pause.)

12 DR. MacMILLAN: Okay. Here is my opening slide.
13 Again, I wanted to focus on United States aquaculture,
14 because it is so different than virtually any place else in
15 the world.

16 (Slide.)

17 DR. MacMILLAN: I would like to cover what
18 aquaculture is in the United States, what our basic culture
19 methods is, because I suspect most people here have been
20 acquainted with terrestrial animal agriculture. Very few of
21 you are acquainted with aquaculture, with the growing of
22 animals in the water.

23 I want to cover very briefly what we use
24 antibiotics for, how we use them and, I might add, we only
25 have two, two antibiotics that we can use in the United

1 States for food fish production.

2 What are our basic controls? That is, what
3 controls do we use to insure the judicious application of
4 antibiotics. And then I would like to, with whatever time I
5 have left, talk about the potential public health risk and
6 canopy measure in the use of antibiotics in aquaculture.

7 (Slide.)

8 DR. MacMILLAN: So, first of all, what is U.S.
9 aquaculture? Well, it is a very diverse industry. The U.S.
10 Agriculture Department recently completed a survey of
11 aquaculture in the United States. The very first one was
12 completed in 1998, and it identified 35 different species of
13 aquatic animals that are raised in the United States; 35
14 species that they could identify or gather enough information
15 on.

16 There is actually about 50 or so different species
17 that are raised commercially under aquaculture conditions.
18 Those species are raised in both fresh water and marine
19 environments, and that becomes a critical issue in
20 determining where risk might lie.

21 The species are raised under warm water conditions
22 and cold water conditions, and that also is a critical factor
23 in identifying where risk could occur or where potential risk
24 is likely to occur. And as we go through the next few days,
25 I would suggest to the participants that temperature and the

1 type of water are going to be key factors that we need to
2 look at.

3 We raise vertebrates and invertebrates. The
4 vertebrates are catfish, trout, salmon, tilapia. The
5 invertebrates are oysters, shrimp and crawfish, just as
6 examples.

7 Crawfish don't use antibiotics. Nobody in the
8 crawfish enterprises use antibiotics. Shrimp farmers in the
9 United States should not be using antibiotics because they
10 are illegal to use. Shrimp farmers in other countries might
11 be using antibiotics. Catfish, trout and salmon producers do
12 have two antibiotics that they might elect to use.

13 (Slide.)

14 DR. MacMILLAN: We raise food animals and non-food
15 animals. A lot of non-food animals are imported into the
16 United States in way of the ornamental fish trade. Sturgeon
17 are raised, a very small industry for sturgeon, and then
18 tilapia are raised. These are both food animals.

19 (Slide.)

20 DR. MacMILLAN: Again, at least 35 minor animal
21 species raised in the United States. They are raised in
22 various types of cultural practices. One of the most common
23 is with the ponds. These happen to be catfish ponds from the
24 Mississippi Delta. Those ponds are generally about three
25 feet deep. They may be 20 acres in size.

1 In previous history, they were 50 acres in size.
2 Harvesting upon that size is really a difficult thing, but 20
3 acres is more manageable. These same kinds of ponds may be
4 used to grow shrimp on the coastal areas of the United
5 States. We have a very, very small shrimp industry in the
6 United States. There is much more shrimp produced in Ecuador
7 and China and Thailand than in the United States. Far more.

8 (Slide.)

9 DR. MacMILLAN: Another culture method is with flow
10 through systems. These are typically used for trout culture.
11 These are earthen bottomed. This particular picture shows
12 an earthen bottomed, earthen sided pond. They may be
13 cemented ponds. The raceways may go from one raceway to the
14 next to the next. The water is used repetitively. In this
15 case it is not.

16 The water quality requirements for the animals
17 raised in this type of aquaculture condition are far more
18 stringent than those in the pond aquaculture conditions, and
19 that is another key factor in identifying where the risks
20 might come in aquaculture practices.

21 The water in these systems goes through very
22 rapidly. Frequently the water right requirements are that
23 you cannot consumptively use the water. It has to go in and
24 out; in and out. In catfish aquaculture you can use the
25 water consumptively, and so those ponds are typically static

1 ponds. Water exchange doesn't occur.

2 Again, those aquatic animals don't require the same
3 level of environment, environmentally stringency, that these
4 colder temperature animals require.

5 (Slide.)

6 DR. MacMILLAN: And then, net pens. Net pens can
7 occur in -- this is where they have a netted area for the
8 aquatic animals to be placed and they are fed there. It can
9 occur in fresh water ponds, in rivers and most frequently in
10 the ocean.

11 Much of the salmon production in the United States,
12 and certainly elsewhere, occurs in net pens in estuarine and
13 in ocean areas.

14 (Slide.)

15 DR. MacMILLAN: There is a small type of system
16 that is being looked at. There is really not any commercial
17 production yet, although people have been in it for just a
18 few years. But it is with closed recirculating water
19 systems. Mostly fresh water systems that replace some of the
20 water daily, and they discharge a small but concentrated
21 eflon (sic.)

22 (Slide.)

23 DR. MacMILLAN: So, antibiotics in U.S.
24 aquaculture. In the United Sates we have two. In other
25 countries there are far more antibiotics available. In

1 Japan, for example, there are 29 antibiotics available for
2 aquaculture. In the United Kingdom there are four. In
3 Norway there are eight. In Chile, anything goes. In
4 Ecuador, anything goes. In China, anything goes. They don't
5 have the same regulatory framework in those countries that we
6 do in the United States.

7 (Slide.)

8 DR. MacMILLAN: So the two drugs that we have
9 available in the United States for food animals only is
10 oxytetracycline and Romet-30. Oxytetracycline has been
11 around for, I guess, 30 years or so. Romet-30, a potentiated
12 sulfonamide, has been around since about the mid '80s. No.
13 Mid '70s to '80 or so. For very few types of aquatic
14 animals, and it is only in the feed.

15 We raise fish in a very intensive way. They are in
16 the water, so they are not very accessible. The only way we
17 can deliver an antibiotic or any other kind of drug, in a
18 purposeful way anyway, is in the feed. There are some water
19 treatments, but those are not antibiotics that are used for
20 the water treatments.

21 (Slide.)

22 DR. MacMILLAN: The NADA is for catfish, salmonids
23 and lobsters only. They each have a pretty long withdraw
24 time of 21 to 30 days. The lobster is for the treatment of
25 gaff kemyia. For catfish and salmonids it is for the

1 treatment of modal --- septicemia, a specific disease of fish
2 caused by erramonis hydrofla for example. And then for
3 catfish it may sometimes be used for enteric septicemia of
4 catfish, although that is not on the label.

5 (Slide.)

6 DR. MacMILLAN: The other antibiotic that is
7 available is Romet-30, the potentiated sulfonamide. For
8 catfish there is a three-day withdrawal time, and this is
9 specifically for the treatment of a disease called enteric
10 septicemia of catfish, ESC. There is a three-day withdrawal.
11 And here, Romet is for the treatment of furunculosis. There
12 is a 42-day withdrawal time.

13 The reason for the difference in withdrawal times
14 is that with the catfish, when they are processed, the skin
15 is removed and this particular antibiotic can concentrate in
16 the skin. With the salmonids the skin is left on. So there
17 is a much more protracted withdrawal time.

18 The interesting thing with Romet 30 is it is hardly
19 used in either industry anymore. With the salmonids it never
20 was particularly valuable because of the long withdrawal
21 time. With the catfish they found alternate ways to manage
22 that particular disease.

23 (Slide.)

24 DR. MacMILLAN: One of the things about aquaculture
25 in the United States is that we don't use antibiotics as

1 growth promotants. Never have, and I can't envision ever
2 doing it for two reasons. One, it is very expensive. But
3 number two, it doesn't work. At least not in fish.

4 We have done some research in my previous history
5 at Mississippi State. We looked at antibiotics in a research
6 situation to see if we could promote the growth of catfish.
7 It didn't work. I am not aware -- and I am fairly familiar
8 with U.S. aquaculture. I am not aware of anybody in the
9 United States that uses antibiotics as growth promotants.

10 (Slide.)

11 DR. MacMILLAN: And there are several reasons why
12 it doesn't work. The most important thing is that the
13 bacterial flora in poikilothermic animals is itinerant.
14 There is no resident flora. Whatever the fish or shell fish
15 is eating, that is what will be in the GI tract of that
16 animal. Or whatever is in the water.

17 If you take a catfish in cold temperatures and
18 don't feed them, their gut, their GI tract, will essentially
19 go sterile. There is no need for the bacteria there. It is
20 sterile. If you change the water quality of the fish, that
21 bacterial flora that you might recover will change.

22 Poikilothermic animals in aquaculture has what I
23 would call several natural barriers to the transmission of
24 antibiotic resistance factors or the occurrence of human
25 pathogens in their system. One is that there are some basic

1 physiological differences between cold blooded animals and
2 warm blooded animals.

3 Those differences become very important when you
4 look at the potential pathogenicity of bacteria. It is very
5 difficult, for example, to take salmonella typhimurium that
6 you recover from a catfish or a tilapia and infect a mammal
7 with that bacteria. There appears to be some sort of
8 biological adaptation, microbiological adaptation, that has
9 to occur before that bacteria can cause disease of any kind
10 in a mammal.

11 (Slide.)

12 DR. MacMILLAN: There is also some basic
13 temperature differences. Cold blooded animals are just that,
14 they are cold blooded. So the culture conditions vary
15 anywhere from say nine or so degrees centigrade, up to 30
16 degrees or so centigrade.

17 Most of the bacteria that we are concerned about
18 thrive not at those colder temperatures, but at the warmer 30
19 degrees and above type temperatures.

20 (Slide.)

21 DR. MacMILLAN: If you look at -- and I am not a
22 food scientist or a food safety expert, but I went through
23 some food safety text and look at the growth parameters or
24 growth conditions, optimal growth conditions anyway, of some
25 of the bacteria that we are perhaps looking at here.

1 Camplyobacter jejuni, no growth at less than 30
2 degrees centigrade. Salmonella species, there is a whole
3 complex of salmonella species, the optimal growth is at 37
4 degrees. That doesn't mean it can't happen at a cooler
5 temperature. It could. But the optimal growth is at 37. E.
6 coli, 37; shigella, 37; vibrio, 20 to 30 degrees centigrade,
7 but that is strictly a marine type bacteria.

8 Forsinia (sic) enterocolitica has a pretty good
9 temperature range, as does lysteria monocytogenes. The
10 warmer the temperature those, even for those bacteria, the
11 faster it will grow. None of these bacteria infect fish.
12 They may occur, but they don't cause disease in those fish.

13 (Slide.)

14 DR. MacMILLAN: There is also no resident microbial
15 flora on the fish. As I mentioned earlier, the bacteria that
16 are in the water at the time, that is what is going to be on
17 or in the fish, the GI tract of the fish. Okay?

18 There is also a very, very large water dilution
19 effect. If you think of raising fish in the ocean, just
20 think how big the ocean is. In most, but not all,
21 aquaculture situations that are profitable, they have a large
22 volume of water at their disposal. That is going to cause a
23 tremendous dilution effect in real life, and that has an
24 impact or potential risk.

25 There is a limited human aquaculture fish

1 environment interaction where people don't usually get into
2 the water to be with their farmed animals. It can happen,
3 but it is usually by accident.

4 (Slide.)

5 DR. MacMILLAN: There are certain management
6 practices in the United States that also limit the potential
7 for bacteria to get into humans from the aquatic environment
8 or for resistance factors, plasmids, for example, to get
9 transmitted on up the line. One, we use clean water.

10 The World Health Organization, about 10 years ago,
11 estimated that about -- let me see -- two thirds of the
12 world's aquaculture was produced in environments where human
13 sewage and homothermic animal waste were purposely put into
14 the ponds or rearing environments for fertilization purposes.
15 Two thirds.

16 In China alone, which produces about 65 percent of
17 all the aquaculture in the world, they still do that. They
18 are changing. They are getting away from the human waste,
19 but they are still doing the homothermic animals. The
20 poultry, the pigs and whatever else. That still goes into
21 aquaculture situations.

22 In Israel and in England and the UK, the placement
23 of animal manures into those aquaculture environments goes
24 on. In the United States that doesn't happen. That has a
25 dramatic impact on the types of bacteria that are present,

1 and hence, a dramatic impact on the relative risk of an
2 aquaculture practice.

3 (Slide.)

4 DR. MacMILLAN: There are very, very few
5 ichthyozoonoses associated with aquacultured fish. Those that
6 have been suspected are of an international flavor. For
7 example, in Ecuador. There has been a suggestion that shrimp
8 were the source of an antibiotic resistant vibrio cholera.
9 Well, Ecuador, in all due respect, their waste management
10 practices are not nearly as good as we have in the United
11 States. Just their basic waste management practices.

12 Another place is in Japan where they -- in this
13 particular case it was because they were eating live fish.
14 And then one is in Israel where somebody got spined from a
15 live fish and they perhaps got exposed to a vibrio that
16 caused -- actually caused a mortality.

17 We have very, very few food-borne pathogens
18 associated with aquaculture fish. The FDA, in 1998, did a
19 salmonella survey of seafoods, wholesale seafoods, and
20 seafoods, in general, had about the same cleanliness, if you
21 will, as red meat products. Red meat products.

22 About two and a half percent of the seafood they
23 tested, in a global sense, had salmonella recovered. The
24 catfish, which were all domestic aquacultured catfish, had
25 about 10 percent salmonella identified. Tilapia, about six

1 percent. These were imported tilapia, not those raised in
2 the United States. And then shrimp that were also imported
3 in the United States, and they had about two and a half or so
4 percent.

5 The MPNs, the most probable numbers for those, in
6 all those cases was very low. We are talking .004 to .022,
7 the most probable numbers for salmonella recovery, meaning
8 that there are very few bacteria present. The place where
9 they found a lot of bacteria was in wild harvested shrimp
10 from India.

11 (Slide.)

12 DR. MacMILLAN: Another challenge to identifying
13 the risk associated with aquaculture is that we are so
14 diverse. We are all minor animal species, so human
15 consumption patterns are going to be very difficult to track.

16 Another real complicating factor and something that
17 has probably promoted some misunderstanding about
18 aquaculture's role, or potential role, in the antibiotic
19 resistance issue is that there are bacteria that grow under
20 aquaculture environments without any antibiotic exposure who
21 are resistant to the antibiotic, and it really becomes
22 important then to track and identify the causes of antibiotic
23 resistance.

24 Is it something that is transferable or not? In
25 this particular case it was not transferable, but it is a

1 very prevalent finding. It appears to be associated the --
2 in certain aquaculture environments with a highly nutritious
3 environment, not with antibiotic exposure.

4 So it is one of the complicating factors that we
5 are going to have to look at as we move forward in
6 identifying ways to identify risk.

7 (Slide.)

8 DR. MacMILLAN: The pathogenic potential of most
9 aquatic bacteria is low. It is not to say that they can't be
10 made pathogenic. They can be made pathogenic. But it takes
11 several passages through a mammal before they can become
12 pathogenic.

13 The microbial flora in the GI tract is itinerant,
14 as well as on the skin. The measures of resistance that
15 aquaculturists and bacteriologists that have looked at this
16 in the aquatic environment -- they have different measures of
17 resistance internationally, and that is a real problem in
18 terms of identifying what the real risk is.

19 It is possible, under laboratory conditions, to
20 demonstrate plasmid transfer from fish pathogens to potential
21 human pathogens. You can go the reverse as well. Human
22 pathogens can transfer plasmids to fish pathogens under
23 laboratory conditions. What we don't know is what the
24 probability of that happening is, and I would suggest to you
25 that 99.9 percent of the time it is a very, very low

1 probability.

2 (Slide.)

3 DR. MacMILLAN: So how do we measure? In large
4 respect, the issue, in my view, for aquaculture comes down to
5 how do you measure the environmental impact of antibiotic use
6 in aquaculture? How do you measure the environmental impact?

7 And that is also going to prove to be a very difficult
8 thing.

9 (Slide.)

10 DR. MacMILLAN: There is a cascade of things that
11 has to happen for an antibiotic that is given to a fish to
12 treat a specific disease; that has to happen in order for
13 that to eventually have an impact on a human pathogen. It
14 has got to go through the fish, it has got to be excreted by
15 the fish, which a large part of antibiotics, the two that we
16 have, can be excreted by the fish.

17 It has got to get into the water column, into the
18 sediment, into the bacteria that are present in the sediment
19 or the water column, and these are mostly aquatic bacteria
20 that won't effect people, and then it has got to get a
21 plasmid.

22 For example, it has got to get transferred from the
23 sedimentary type of bacteria to the terrestrial type of
24 bacteria and then, from there, into a human and then, from
25 there, to cause disease and then it has to be a type of

1 bacteria that is resistant to a particular antibiotic that a
2 person would use. Quite a cascade.

3 What that means though is that it is going to be
4 very difficult to quantitate the probability of that
5 happening. I would suggest to you that the use of
6 antibiotics in U.S. aquaculture has an undetectable impact on
7 the prevalence of human pathogenic bacteria resistant to
8 bacteria.

9 There is an overwhelming bit of qualitative data
10 that supports that contention. There was a report put out in
11 1997 by a couple of scientists from the United Kingdom
12 entitled, "The Use of Antimicrobial Agents in Aquaculture."
13 It is a report to the Advisory Committee for the Microbial
14 Safety of Food, the ACMSF working group on antimicrobial drug
15 resistance.

16 In this report they shared the same opinion that I
17 do about the relative risk of aquaculture. It is very, very
18 low. It is not impossible, but it is very, very low. What
19 they identified as the greatest risk is with the use of
20 antibiotic in ornamental fish. That is where, from their
21 view, there is the greatest potential for the transfer of
22 resistance from the fish to people.

23 The one last thing is that relative risk is going
24 to be dependent on water temperature, the species raised and
25 the presence of human or animal waste. Thank you for your

1 forbearance.

2 (Applause.)

3 CHAIRWOMAN LATHERS: Thank you. We will now take a
4 break, and, please, be back here at 10:30.

5 (Whereupon, a brief recess was taken.)

6 CHAIRWOMAN LATHERS: I think it is time to begin.
7 We have now completed our discussions of antibiotic use in
8 ruminants, poultry, swine and aquaculture. We will now begin
9 the next session with a discussion of antimicrobial drug
10 discovery and development by Dr. Jeffrey Watts.

11 Jeff has a BS in microbiology and a master's in
12 microbiology, both earned at Louisiana Tech University, and
13 he tells me that as of just February 15th he has completed
14 successfully his Ph.D. dissertation defense.
15 Congratulations, Jeff.

16 (Applause.)

17 CHAIRWOMAN LATHERS: That was in biological
18 sciences, and he has earned this at Western Michigan
19 University. He is presently a clinical research scientists
20 too in worldwide product division at Pharmacia and UpJohn
21 Animal Health in Calamazoo. Jeff.

22 **ANTIMICROBIAL DRUG DISCOVERY AND DEVELOPMENT**

23 **By Dr. Jeffrey Watts**

24 DR. WATTS: Thank you, Dr. Lathers. What I am
25 going to do over the next few minutes is talk about

1 antimicrobial discovery in animal health, and particularly, I
2 am going to talk about the impact of the resistance issues on
3 discovery programs in animal health.

4 (Slide.)

5 DR. WATTS: What I am going to do is briefly frame
6 up the resistance issues, then I am going to talk about the
7 antimicrobial discovery programs, starting with the human
8 programs and moving into the animal health programs. It is
9 essential to do it this way because the animal health
10 programs, as you will learn, very much live at the knee of
11 their parent.

12 Then we will talk about the issues that effect
13 antimicrobial discovery in animal health, what I call the
14 environmental factors, the impetus to move away from broad
15 spectrum compounds, the impact of the framework document;
16 should we move toward vaccines, the other things that the
17 antibacterial support groups do in animal health companies,
18 including service support activities, and then wrap up with
19 some comments on the future of discovery in animal health.

20 (Slide.)

21 DR. WATTS: Just to briefly frame this, as you
22 know, the emergence of resistance organisms in human and
23 veterinarian medicine is of great concern. The more
24 resistant organisms tend to be predominantly those nosocomial
25 in humans, with the veterinary contributions primarily

1 through zoonotic pathogens.

2 There have been short-term responses to these
3 issues, and these include things like the development of use
4 guidelines, the development of formularies and therapeutic
5 guidelines and restricted uses of selected compounds.

6 (Slide.)

7 DR. WATTS: When you talk about discovery, you are
8 looking more than two to three years out. You are looking
9 usually at seven to 10 years out. So what are the longer
10 term effects, looking at 2005 and beyond? Will the
11 antibiotic resistance issues prevent the introduction of new
12 antimicrobial agents in food animals? That is the key
13 question.

14 Will companies chose to stay in the food animal
15 markets or in animal health at all? And will clinicians have
16 therapeutic options for current pathogens or for new emerging
17 pathogens?

18 (Slide.)

19 DR. WATTS: Let's talk a little bit about the human
20 discovery programs. The cost of developing a new compound is
21 very high. The estimates for a new human use antibiotic are
22 \$125 to \$350 million. I have heard estimates on some of the
23 newer compounds of more than \$500 million.

24 The time it takes from the time that compound is
25 initially discovered to the time it is introduced to market

1 is 10 to 12 years; however, the markets tend to be quite
2 large, or can be quite large, with markets easily being \$500
3 million and several compounds making over a billion dollars
4 per year.

5 (Slide.)

6 DR. WATTS: Over the last few decades there has
7 been several strategies for countering resistant organisms.
8 These are what I term, for the most part, incremental
9 improvements. It is improving existing structures.

10 We have seen this happens with beta-lactams and
11 various generations of cephalosporins, the fluoroquinolones,
12 the antibiotic inhibitor combinations, what I call re-trading
13 of older compounds, things like the amoxicillin clavulanate
14 combinations, which can be quite successful. Augmentin, at
15 its peak, I believe sold over \$2 billion a year worldwide.

16 The problem with these types of strategies is the
17 resistance mechanism. The basic mechanism is already in
18 place, and all it takes is a minor modification by the
19 organism to ramp resistance back up. So optimally, what we
20 should do is screen for compounds with new mechanisms of
21 actions.

22 (Slide.)

23 DR. WATTS: And so, our classic screening program
24 involved a streptomycetes type of fermentation. We would
25 then screen for inhibitory activity. We would discard any

1 hits here if there was not activity, or we would discard if
2 there were no hits, no activity or any hits that turned out
3 to be nuisance antibiotics.

4 If it was active, if it appeared to be unique, then
5 we would go through a re-fermentation process. The activity
6 would be confirmed. We would scale up the chemistry efforts,
7 we would identify the structure, then we would chemists at it
8 into a synthetic chemistry program to develop new analogs.

9 (Slide.)

10 DR. WATTS: In the '80s this system collapsed, and
11 the reason it collapsed was we had over 6,000 antibiotics and
12 the system we used could not recognize new structures. Also,
13 the antibiotic business was changing. There were only a few
14 mechanisms of action. The customers were becoming rather
15 disgruntled. They could only stand so many third generation
16 cephalosporins being introduced into the marketplace, and
17 there was also a question of whether or not they even needed
18 new antibiotics.

19 (Slide.)

20 DR. WATTS: So the current paradigm is that now
21 what we are doing is we are using a molecular target. This
22 is targeted as our mechanism of action. We clone and express
23 this target, we devise an assay, we now screen chemical
24 libraries and natural products through this assay, we then
25 select our lead compounds, and again, we throw chemists at it

1 into an analog to develop usually thousands of analogs to
2 screen from, and this is what has been termed a mechanistic
3 screening program.

4 (Slide.)

5 DR. WATTS: And through the older techniques of
6 incremental improvements -- and we are starting to see some
7 of the -- at least adding components of mechanistic screening
8 programs. We are seeing a variety of compounds come to
9 market in human medicine.

10 We are seeing the broader community use agents,
11 which include the extended spectrum fluoroquinolones, the
12 glycosides; we're seeing macrolides, particularly the
13 azolides. The ketolides are in development and moving
14 through the pipeline.

15 We are also seeing narrow spectrum compounds
16 primarily focused on the very resistance organisms, such as
17 the enterococci and resistance -- staphylococcus, the improved
18 glycopeptides, synergid, the everninomycins and the
19 oxazolidinones represented by ---

20 (Slide.)

21 DR. WATTS: So let's talk about the animal health
22 markets. The animal health markets tend to be much smaller
23 than the human health markets. Generally, they are about one
24 tenth in size. They are usually split among various animal
25 groups, and these animal groups have varied use practices and

1 preferences.

2 Multiple indications are usually necessary in order
3 for a compounds to be successful in animal health. And
4 because of these multiple indications and varied use
5 practices in preferences, there has been a preference toward
6 broad-spectrum compounds in most areas of veterinary methods.

7 However, as I said, animal health companies live at
8 the knee of their parent. The parent company is relied upon
9 for large scale screening, the chemistry efforts to expand
10 the template, the initial in vitro toxicity screen, in vitro
11 activity and toxicity screen, and even if you don't work in a
12 class that your parent is working in, you still rely heavily
13 upon them for things like path/tox services, formulation,
14 pharmacokinetics and manufacturing production. You live in
15 their infrastructure.

16 (Slide.)

17 DR. WATTS: So the way the process would work is
18 that we would develop a target compound profile. We would
19 probably look at a large single market for the first
20 indication. We would have to define what that market would
21 look like seven to 10 years in the future. We would have to
22 know what our current competitors are, and we probably have
23 some ideas of what other compounds are in the pipeline that
24 will be our future competitors.

25 And we have to know the compound attributes,

1 particularly those that give us a competitive advantage. And
2 if you look at BRD as an example here, in the 1980s we were
3 driven by residues. We saw ceftiofur come to market with no
4 withhold. In the early 1990s this was changed into a
5 convenience issue where we saw tilmicosin become a dominant
6 player

7 And so the question becomes, as we head into the
8 2000s, will resistance become a dominant issue and a
9 competitive advantage?

10 For the most part, the animal health discovery
11 companies obtain their lead compounds from the human health
12 program. We also look at the available in vitro activity and
13 toxicity data, usually using a human organism as our
14 veterinary surrogate.

15 For example, of course, you look at data for E.
16 coli. What you would look for, if you were interested, is
17 does this culture have pestoral activity. I would look at H
18 Flu data. Does it have streptococcus activity? I would look at
19 streptococcus pneumonia data. So you are making that
20 transition from those human pathogens.

21 You would screen for activity specifically against
22 your veterinary pathogens. These would be in vitro screen,
23 MIC determinations, you would then screen through various
24 mouse models, target animal models and you would like for
25 demonstrated efficacy and safety at this time.

1 At this time you would transition to development,
2 and this is where the discovery scientist plays a key role,
3 in that usually the discovery scientist has to be an advocate
4 for its compound, and they are responsible for successfully
5 transitioning those compounds from discovery into
6 development.

7 (Slide.)

8 DR. WATTS: If we look at the compounds that are
9 currently available and the programs they came out of,
10 Tilmicosin came out of a animal health program. The
11 ceftiofur, pirlimycin, enrofloxacin and chloramphenicol
12 originally arose out of large corporate screens for compounds
13 to be used in human medicine.

14 This was the year of the first publication on these
15 articles, and one of the things you need to keep in mind is
16 if you see ceftiofur at 1987, that means that compound was
17 originally looked at in about 1980. If we look at
18 florfenicol at 1980, that means the screen for that compound
19 was probably in the mid '70s.

20 Pirlimycin, lincosamides, in 1985 first described.

21 I can tell you that the lincosamides screen for pilimycin
22 was discovered in the mid '70s. So, when you start talking
23 about new compounds that you would just introduce, many times
24 those compounds are 10, 15 or 20 years old.

25 (Slide.)

1 DR. WATTS: So the question becomes -- is as we see
2 the mechanistic screening programs kick in in human medicine,
3 as we see new antibiotic and new antimicrobial classes with
4 new mechanisms of action being introduced hopefully over the
5 next 10 years, then will animal health be allowed to
6 participate and be able to participate in this revolution.

7 So one of the things that we need to look at are
8 the environmental factors. Again, the changes in clinical
9 use patterns, the argument over whether or not we should be
10 developing narrow versus broad spectrum compounds, the
11 regulatory environment, particularly the framework document,
12 and prevention strategies. Should we move to just
13 vaccinations and that becomes our dominant way of controlling
14 diseases and they replace antimicrobial agents?

15 (Slide.)

16 DR. WATTS: There is an excellent talk at ICAC this
17 year by Dr. Bob Mollering on the argument of narrow versus
18 broad spectrum compounds in human medicine. Narrow spectrum
19 compounds target a given class of organisms. Usually gram
20 positive or gram negatives. They target a specific genus or
21 species even, while broad -- the definition for broad tends
22 to be less defined.

23 We usually know a broad spectrum compound when we
24 see it, in terms of the type of spectrum it covers, but most
25 people think of broad spectrum compounds as those that cover

1 both gram positive and gram negative organisms.

2 (Slide.)

3 DR. WATTS: The advantages to a broad spectrum
4 compound are that if you have an unknown etiological agent,
5 you can cover it or have a better chance of covering. You
6 can cover polymicrobial infections, and it provides peace of
7 mind for the clinician.

8 The disadvantages are that there is a greater
9 impact on normal flora, what is called the innocent bystander
10 effect, selection of resistance in multiple species of
11 organisms and it may impart a false sense of security to the
12 clinician.

13 (Slide.)

14 DR. WATTS: The advantages of narrow spectrum are
15 you have reduced selection for resistance, it is targeted
16 against selective pathogens, and you have a reduced innocent
17 bystander effect. The disadvantages are you need a precise
18 diagnosis, and it cannot be used to manage polymicrobial
19 infections.

20 (Slide.)

21 DR. WATTS: This is the way Dr. Mollering summed up
22 his talk, and I think it is the best way I have seen of
23 summing up the argument of narrow versus broad. "Narrow is
24 good, if you can live with it, and broad is bad, unless you
25 need it."

1 (Slide.)

2 DR. WATTS: So, should animal health companies
3 focus only on narrow spectrum compounds? The thing we have
4 to realize is that it will require more compounds in the
5 portfolio. That is, a company, instead of living on one or
6 two compounds, now has to manage two, three, four and five
7 compounds.

8 You are going to have to have multiple classes of
9 compounds, and that is difficult to do if your parent program
10 is heavily invested in one class. So you are going to have
11 to go outside your company in order to find additional
12 classes.

13 You have to provide support for each compound.
14 Support means path/tox, formulation, manufacturing,
15 marketing. You will have limited indications for each
16 compound and limited label expansions. The problem you also
17 have is that marketers will tell you there is difficulty
18 marketing narrow spectrum compounds, particularly in markets
19 where there are broad spectrum agents available. In a market
20 where there is a narrow and a broad, the broad always wins
21 and always dominates the market.

22 (Slide.)

23 DR. WATTS: The regulatory climate at this point in
24 time primarily revolves around the framework document, and I
25 have tried to summarize the categories here, with category

1 one being the compounds considered essential for treatment of
2 serious or life-threatening disease in humans.

3 Category two is important for treatment of serious
4 disease, but alternative therapy exists, and category three
5 is limited or no use in human medicine.

6 (Slide.)

7 DR. WATTS: What is the impact of a framework
8 document? Short-term, category one blocks animal health
9 development for new classes in food animals. Group two
10 limits development to those indications with low risk of
11 resistance development, and category three will limit
12 compounds to those of low potency, toxicity problems or high
13 levels of resistance in human pathogens.

14 This links the veterinary use to the human use in
15 terms of both availability of drugs, particularly
16 availability of drugs in human medicine to treat specific
17 infections, and the resistance levels in human pathogens.

18 (Slide.)

19 DR. WATTS: Another thing we have been told is we
20 should explore vaccines as an alternative to antimicrobial
21 agents. I believe that vaccines are important and they are
22 an important component of disease management programs. They
23 should be used when and wherever possible. I think
24 prevention is the key.

25 However, vaccines may not replace antimicrobial

1 agents, and the reasons are that effective vaccines are
2 difficult to develop for many bacterial pathogens. They
3 target only one agent or one, so you have to have a
4 multivalent vaccine.

5 One of the things that we have very little
6 information about, but something that may be important, is
7 that vaccines are a selective pressure. They may change
8 pathogen distributions and they could change pathogen
9 distribution to a more resistant pathogen. We just don't
10 have a lot of information on that.

11 Vaccine market cycles are shorter and the vaccine
12 value tends to be much lower. That is, because the cost of
13 vaccines tend to be much lower than it is for antibiotics,
14 those market values tend to be much lower. You tend to have
15 to manage many more vaccines in your portfolio in order to
16 get the same value that you would for one single antibiotic.

17 This is truly an example where an ounce of prevention is not
18 worth a pound of cure.

19 And also, one of the things that may be required is
20 surveillance of effect on pathogen distribution. It may be
21 necessary in order for us to understand what is going on in
22 these various management systems.

23 (Slide.)

24 DR. WATTS: The service support activities. This
25 is what I jokingly refer to as what your discovery people do

1 in their free time. Most microbiology expertise in animal
2 health companies reside in the discovery program. Usually
3 more than 50 percent of their time and resources are spent in
4 this area each year.

5 You have to remember that most of these groups are
6 fairly small. A group with 10 to 15 people would be
7 considered quite large for a dedicated antimicrobial
8 discovery program in animal health.

9 And these are sort of the things that they do, the
10 activities that they may be involved in: Generating MIC data
11 for label expansions and extensions, conducting MIC studies
12 or in vivo to meet regulatory requirements, a lot of the
13 resistance monitoring efforts reside in the discovery group,
14 and also, susceptibility test development to support those
15 compounds. As resistance needs and monitoring needs have
16 ramped up, that is taking time away from discovery efforts.

17 (Slide.)

18 DR. WATTS: So what is the future of animal health
19 antimicrobial discovery compounds? The compounds currently
20 in development will probably be the least effective. They
21 will probably make it to market with some sort of indication.

22 It may be a limited indication at first.

23 Many of these programs will be re-focused onto the
24 companion animal markets because the resistance issues have
25 not been as great a concern there. The food animal markets

1 will be limited to those with reduced resistance concerns.

2 The availability of new compounds and the decreased
3 utility of existing compounds in human medicine may allow the
4 use of some of the newer classes of antibiotics in food
5 animals, but that is a longer term scenario. And the gap in
6 food animal compounds will begin to occur about 2005, unless
7 directed efforts in this area remain in place.

8 (Slide.)

9 DR. WATTS: In order for this to happen, one of the
10 things that the animal health companies have to do is their
11 management has to have the resolve to stay in the game, and
12 they have to have the resolve to make sure the programs are
13 adequately resourced.

14 Discovery programs must build in resistance as part
15 of the target compound profile. That is essential. And so
16 we would do things like mutation frequency studies,
17 resistance mechanism determinations, dose/use patterns that
18 minimize resistance, and I will guarantee you that as new
19 compounds come to market that are safer in terms of
20 antibiotic resistance, that this will become a marketing
21 issue once these compounds to the market.

22 I believe that wraps me up at this point in time.

23 Questions?

24 (Applause.)

25 CHAIRWOMAN LATHERS: Thank you very much. Are

1 there any questions?

2 (No response.)

3 CHAIRWOMAN LATHERS: Thank you again. We now move
4 on to our next topic, antimicrobial new animal drug
5 applications, a review process overview. Dan Benz will be
6 presenting this.

7 Dan has earned a BS at the University of Illinois
8 and a master's at Colorado State University. He has a Ph.D.
9 in nutrition from Texas A&M University, and he is presently
10 an animal scientist in the ruminant drug team in the division
11 of biometrics and production drugs at the Office of New
12 Animal Drug Evaluation at the Center for Veterinary Medicine.
13 Dan.

14 **ANTIMICROBIAL NEW ANIMAL DRUG APPLICATIONS**

15 **REVIEW PROCESS OVERVIEW**

16 **By Dr. Dan Benz**

17 DR. BENZ: Thank you. You may wonder why I am here
18 this morning. Well, I wondered that too. It is not because
19 one Friday afternoon I was sitting around my office and
20 somebody came in and said, "What are you doing the 22nd of
21 February? Are you busy?" And I said, no. Well, they said,
22 you can give a speech.

23 It is not because this was originally scheduled to
24 be between 11:00 and 11:30 you would have lunch and somebody
25 said, well, you can make it short and go to lunch early. It

1 is not for all those reasons. The actual reason I am here
2 today was that there was a request made that we tell John Q.
3 Public just what is required to support an NADA.

4 You know, there is a lot of talk about putting a
5 lot of additional requirements on the drug companies, so what
6 is currently required? And that is what I am going to talk
7 about today, and this is pretty much going to coffer all new
8 animal drug applications, not just antimicrobial, and I will
9 show you some differences when we get into those.

10 What are the contents of an NADA? Well, what
11 supports an NADA? Well, the first thing we have is a cover
12 letter from the sponsor. They are going to tell us what they
13 want; a description of the request. We would like to get
14 this compound approved for this type of animal, et cetera.

15 We have a lot of miscellaneous information, patent
16 information, marketing exclusivity information that we tend
17 to put in there. We have a FDA 356V. I am not sure what the
18 356V stands for, other than I assume it was the 356th
19 numbered form that FDA had. I know the V does stand for
20 veterinary.

21 That form is based on the regulations 21 CFR 514.
22 If you want to look them up, that is where it is. A very
23 important thing that I have bolded, underlined and italicized
24 is it must be signed by a responsible official or authorized
25 agent by the company. And if it is a foreign company, they

1 have to have somebody in this country that has the authority
2 to sign them.

3 (Slide.)

4 DR. BENZ: Now, for the quiz of the day. How many
5 can read this? I know you can't, but we are going to talk
6 about it in my ensuing slides. But I wanted you to see what
7 an application looked like besides NADA. Drug product, some
8 information here below, some instructions for use, Paperwork
9 Reduction, a little spot for a doc unit to use. Also, it was
10 nice to figure out how to use Adobe Acrobat and get it into
11 PowerPoint.

12 (Slide.)

13 DR. BENZ: A little information on the back side.
14 Some fine print. Every good form has got to have its fine
15 print that you sign and don't know about. And a place for
16 the signature and their title with the date.

17 (Slide.)

18 DR. BENZ: What is on the form FDA 356V? Well, one
19 of the first things is drug product information, the
20 established proprietary names. For example -- and I am going
21 to stick away from the animal area so I can't get in trouble
22 by particularly picking anybody's product out.

23 Acetaminophen. Tylenol in the human area, the
24 established proprietary. Advil, Ibuprofen. So there is a
25 couple of examples.

1 Dosage form. What form will that be? Will it be
2 an injectable? Will it be an oral in the feed? So we want
3 to know what type will be used up front.

4 Proposed indications for use. Whether it is going
5 to be a production or increased average daily gain, increased
6 milk production, you can go down that, or some therapeutic
7 use. The species of the animal that it will be used in:
8 Cattle, swine, sheep, goats, horses, dogs, cats; whatever.
9 And its proposed marketing status, whether it is going to be
10 prescription or over-the-counter.

11 And I suspect, some time when this is updated, it
12 is going to have three prescription OTC in for the new class
13 of veterinary feed directives. But right now we have two on
14 the form.

15 (Slide.)

16 DR. BENZ: Some additional information.
17 Applicant's name and address. We want to know where they are
18 doing business. The type of application, whether it is an
19 original or a supplement. Original means it is the first
20 time we have ever brought it in. Maybe it is a new chemical
21 entity. We have never looked at it before. A supplement is
22 something that would be approved products already on the
23 market and the firm is trying to make some sort of change to
24 that.

25 A reason for the submission. What are you trying

1 to do? The good old Paperwork Reduction Statements. We have
2 to have that in there to be in compliance with our OMB
3 regulations and Paperwork Reduction Act. And some
4 instructions for submitting an NADA. How many copies we
5 want, et cetera, are all on that form.

6 (Slide.)

7 DR. BENZ: As I said, that was on the second page.
8 There is appropriate sections, and these sections are
9 checked as necessary. I will give you a couple of examples
10 which I will go into later. But you don't really have a need
11 for human food safety in companion animals. So that section
12 would not be checked.

13 Also with companion animals the environmental
14 assessment is a lot easier. Lots of times they get a
15 categorical exclusion. So those types of things may or may
16 not be checked.

17 And I said the fine print. That is the legally
18 binding statements. No one was debarred under the Food Drug
19 and Cosmetic Act will be involved in any capacity. That came
20 out of the generic scandal. And finally, a warning. A
21 willingly false statement is a criminal offense. In my mind,
22 that says FDA does mean business.

23 (Slide.)

24 DR. BENZ: We are going to go down the sections;
25 right down the 356V. I know you couldn't read it. That is

1 why we came to these slides. We have the identification of
2 the compounds, table of contents and summary. Particularly
3 the summary to describe the chemistry of the proposed drug so
4 we know what it is.

5 Its clinical purpose. Again, whether it is
6 therapeutic, a growth promoter. And the summary of the
7 laboratory and clinical studies to support that application.

8 (Slide.)

9 DR. BENZ: Labeling. We have product labeling. It
10 may be the labeling on a vial. If you also have any
11 packaging that goes along with it. If a vial comes in a box
12 and that has labeling, we want to know that.

13 Package inserts. If you go to CVS and pull out a
14 tube of ointment and you have got an insert, we would also
15 look at the same type of insert that would be available for
16 an animal drug. And then, if it is a feed, we want to look
17 at type A, B and C medicated labeling or the feed labeling.

18 The reason that we need the labeling, besides the
19 fact that it will be put out for public display later on, is
20 we also look at the labeling in conjunction with the safety
21 and effectiveness to see if the two coincide, if the labeling
22 is supported by the safety and effectiveness data.

23 (Slide.)

24 DR. BENZ: Okay. The components and composition
25 section, a list of all articles used as components, the

1 statement of the composition, a description of the
2 fermentation of the antibiotic drug; some sense of how the
3 products are made.

4 (Slide.)

5 DR. BENZ: Again, more on manufacturing methods,
6 facility controls, the personnel that are involved, the
7 facility equipment, a description of the drug synthesis, how
8 it was made, raw material controls, manufacturing
9 information.

10 (Slide.)

11 DR. BENZ: And additionally, finished product
12 controls, stability program, container packaging, lot control
13 number system. In a nutshell, how was the product made and
14 can they make it again and come up with the same consistent
15 product over and over.

16 And then finally, we have a way, with a lot control
17 number system, et cetera, to monitor that product. You know,
18 if some product gets out in the marketplace and it is
19 recalled, you have to know where it came from, and that is
20 where the lot control number system comes from. So we are
21 looking at all -- the complete manufacturing process.

22 (Slide.)

23 DR. BENZ: Samples. We hand ask for samples upon
24 request. We seldom do. I assume there must be a reason some
25 time along the way that we have asked for samples. Examples

1 that I could think of is if you had a question of is there an
2 active ingredient in this drug or that type of thing.

3 And again, here is one that I said earlier that
4 only applied to certain ones as applicable. Analytical
5 methods for residues, only to food producing animals. Again,
6 we would not look at looking for residues in companion
7 animals.

8 (Slide.)

9 DR. BENZ: We have to have evidence of safety and
10 effectiveness, and this includes human food safety, target
11 animal safety, user safety, and again, effectiveness.

12 (Slide.)

13 DR. BENZ: Human food safety. We are looking drug
14 residues in animal tissues. Those include meat, milk, eggs;
15 you name it, what we could call as edible tissue. We look at
16 acute toxic response. An example is what would happen, you
17 know, to children who are allergic to peanuts, get a peanut
18 and have acute response. They might go into convulsions.

19 We are also looking at those kinds of things with
20 residues of drugs. What would be a short-term effect if they
21 got a lot of the drug, and then a chronic exposure toxicity
22 or a long-term exposure. What happens to them.

23 We also look, as part of that, antimicrobial
24 resistance and pathogen load. Those have been called 558.15
25 studies, salmonella sheddings; they have gone by a lot of

1 different names. Dr. Cooper is supposed to give that
2 presentation next.

3 (Slide.)

4 DR. BENZ: Target animal safety. We have to have
5 studies or reports to demonstrate the cumulative effect of
6 the drug on the animals, such that the drug does not
7 adversely effect the treated animals. Simply put, does the
8 drug harm the animal? We are going to look to see if the
9 drug harms the animal at all.

10 (Slide.)

11 DR. BENZ: User safety. We look at hazards
12 associated with manufacturing; direct. Is there any hazards
13 to the occupational exposure to site when the drug is
14 manufactured. Indirect, such as manufacturing emissions;
15 hazards associated with administration to animals.

16 An example might be that you have a product that is
17 very safe in the animal, but if the human took and injected
18 themselves by accident, it could be very toxic. So we want
19 to look at that.

20 Hazards associated with the use of air, water and
21 solid waste contaminated by use and disposal of the drug. An
22 example that I could give you would be that if you have a
23 drug that you give every day, if it is an injectable and you
24 are giving it to 1,000 animals, what are you going to do with
25 those 1,000 syringes? We look at those types of

1 environmental concerns that go along with that.

2 (Slide.)

3 DR. BENZ: The effectiveness determined by experts,
4 those experts such as myself by training experience. Must of
5 us have various degrees. We have some experience in that
6 field. That is what we are paid for.

7 We, again, fairly and reasonably concluded that the
8 drug will have the effective reports or it is represented to
9 have the conditions of use to prescribe recommended suggested
10 labeling. As I said before, we are looking at the labeling
11 and effective data and see that the two match and what is
12 actually in the submission will support that labeling and
13 will that product be used in the marketplace in a reasonable
14 manner.

15 (Slide.)

16 DR. BENZ: The effectiveness is based on
17 substantial evidence, and I won't describe what that is --
18 that would be a whole other presentation -- consisting of one
19 or more adequate and well controlled investigations, such as
20 a study in a target species, a study in laboratory animals, a
21 field investigation, bio equivalent studies and in vitro
22 studies.

23 And those would depend on what you were trying to
24 do. You might have a model that would predict a disease
25 condition. It might be appropriate with an in vitro study or

1 a laboratory study. Some other types of study might not be
2 appropriate to do that. So you would have to use what was
3 appropriate for that condition.

4 (Slide.)

5 DR. BENZ: Another section is our GLP good
6 laboratory compliance section. There is a set of regulations
7 that tell you how you should collect data in a correct
8 manner, such as data signed, dated, it has gone through a QA
9 unit, a quality assurance unit. We feel pretty comfortable
10 about it so that the firm has attested that they have
11 collected the data that needs to be, such as target animal
12 safety and human food safety under those conditions and have
13 verified that.

14 Another section is environmental assessment or EA.
15 The use, manufacture and disposal of that drug does not
16 propose a significant environmental impact and an NADA must
17 have an EA or a claim for a categorical exclusion. The
18 categorical exclusion comes in for such things as companion
19 animals.

20 Another example would be that you have a drug that
21 is on the market. You are going to change the labeling to
22 clarify something, but you are not going to change the
23 overall exposure of the drug in the population. You might
24 want to rename or reclassify the genus or a species of some
25 antimicrobe.

1 (Slide.)

2 DR. BENZ: Our Freedom of Information summary.

3 That is the information that is for public disclosure that we
4 make available. That includes everything but proprietary
5 information, such as chemistry and manufacturing; how the
6 product was marketed.

7 That is available in the dockets manager branch or
8 on our web site for anybody to look at. Such things that are
9 in there are description of the effectiveness data that was
10 used to support the application, description of the target
11 animal safety, human food safety and there is a few other
12 things. But that is the kind of stuff that we are looking
13 at.

14 And then there is a section called "other" that I
15 have never used, but every application has to have a good
16 other just to catch everything else.

17 (Slide.)

18 DR. BENZ: Now, I told you what you find that the
19 drug company or the sponsor submitted, but if you wanted to
20 go in and look at an NADA and see what CVM has got in there,
21 the agency? Basically, these are the documents that are in
22 an NADA that we have generated.

23 Review. I generate animal science reviews. We
24 have got people that generate veterinary reviews, human food
25 safety. But our interpretation of the data and how it would

1 support that application. We have gone and looked and this
2 is my scientific review.

3 Sometimes we have meeting minutes or memorandum of
4 conference. We may have had a meeting with the firm. We
5 have sat down around a table and discussed issues and those
6 issues are of importance, so we want to document in the field
7 that we have had this meeting. Sometimes we have internal
8 meetings with our supervisors or other colleagues. We want
9 to document what happened there.

10 We have that and it goes into the file, so that if
11 five to 10 years, if these types of questions come up again,
12 we can look and say, well, this is what those types of
13 decisions were based upon.

14 Sometimes we have a document summary, which is kind
15 of a historical basis of where that submission is moved, what
16 is going on, whether it is human food safety, effectiveness,
17 target animal safety, but the status at the time. If the
18 drug is going to be approved, we have a memorandum
19 recommended approval, which is kind of obvious to the name.

20 That memorandum has a lot of administrative
21 information. Basically it tells those in our supervisory
22 chain, which in my case is Dr. Lathers, that I have dotted
23 all the I's and crossed the T's and followed everything along
24 the way and that approval is following our policies and
25 procedures, and they can feel comfortable in signing off and

1 saying, yes, we should recommend this approval.

2 And it is a great place for them to pick up and
3 say, what is going on in this application; in a four to five
4 page document and say this is all the history I need to know.

5 Sometimes we have an administrative memorandum.

6 That administrative memoranda can be because the
7 data didn't quite address a situation. We had some concerns,
8 but there was a policy decision that set that aside. It
9 could be policy decisions that came from above. So that is
10 administrative memoranda.

11 A draft regulation. CVM drafts a regulation which
12 eventually ends up in the Federal Register for approved
13 products. That is in there. That is something that we also
14 send forward. We try to provide what will end up in the CFR
15 and the Federal Register; how we want it.

16 And then there are letters, letters to the sponsor
17 that are necessary. Sometimes there is a really nice letter
18 that says, dear company, your application is approved and you
19 can begin marketing it. Sometimes we have letters that says
20 please try again, these are the others that we would like
21 some additional information and please come back and give us
22 that information, and we will re-evaluate your request.

23 And, that is the end of my speech. Any questions?

24 (Applause.)

25 CHAIRWOMAN LATHERS: There is a question for Dan?

1 Dan, would you wait just a moment, please. Would you use the
2 microphone, please.

3 MS. MELLON: Hi. My name is Margaret Mellon. I am
4 from the Union of Concerned Scientists. From what I -- from
5 what you have presented, there doesn't seem to be any
6 information collected by the agency on usage. I mean,
7 whether approved compounds are actually used, in what amount
8 and in what animal systems.

9 Is that true? And if you don't get it in this
10 process, do you get it in any other process?

11 DR. BENZ: There isn't any information collected
12 here because this is the pre-approval process, and it would
13 be hard for us to estimate how much would be used, other than
14 there is some estimation in the environmental assessment
15 because they have to have some idea of what kind of impact.

16 We have a whole office, the Office of Surveillance
17 and Compliance, that looks at products post-marketing;
18 whether they are used in accordance with label directions,
19 how much there is used, et cetera, and that is their complete
20 function, is surveillance and compliance.

21 MS. MELLON: Does the agency make that available in
22 a report, like this is how much of a particular antibiotic
23 that has been used in a particular system in 1998 so we could
24 track it over time to see whether antibiotic use is going up
25 or down in particular systems to get a better idea of

1 exposure?

2 DR. BENZ: I really don't know the answer, because
3 I am from the Office of New Animal Drug Evaluation. I do the
4 pre-approval, and I am more on will the product be safe and
5 effective. If there is anybody here from Surveillance and
6 Compliance that could answer that -- or we can leave it for
7 later today. I really don't know.

8 MR. : --- animal drug experience report.

9 DR. BENZ: Well, there is a drug experience report
10 that would tell how much the drug -- each owner of an NADA
11 that is approved must report to the agency annually in
12 something called a drug experience report. It tells us how
13 much the drug is used.

14 And I don't know if it is summarized across
15 companies or anything in public made available, but we do
16 have some indication --

17 MS. MELLON: We have tried to locate such reports
18 and have never been able to do so. But if they are
19 available, we would like to hear about it.

20 CHAIRWOMAN LATHERS: Dr. Thompson.

21 DR. THOMPSON: I am not from surveillance and
22 compliance, but I will try to answer your question. We do
23 get information, as you are probably aware, in the drug
24 experience reports, but that is targeted specifically to the
25 individual drug, and most of that is considered proprietary

1 information.

2 There are some problems, which we have stated in
3 the framework document, with how we currently collect the
4 information, and we are in the process of trying to make some
5 changes in terms of changing our regulations to provide a
6 better basis for tracking drug usage information in the
7 future and providing a better linkage to the resistance data
8 that we are collecting through the National Antimicrobial
9 Resistance Monitoring System.

10 The questions about how the information will be
11 released publicly, we don't really have an answer for that
12 yet. We are looking at that issue in terms of providing
13 better public information in the future on that. But some of
14 it is considered proprietary information and is not
15 releasable by the agency.

16 MS. MELLON: Well, I do -- I am glad that the
17 agency recognizes that it is a problem, and I guess I would
18 just say that there are ways around proprietary information,
19 aggregating data and all that, which I know you have thought
20 about.

21 But I would just encourage you to go in that
22 direction. It is a real hard issue to address, either from a
23 health standpoint or a public policy standpoint, when you
24 don't have any idea, really, of how much antibiotic is being
25 used, where and what the trends are over time.

1 DR. BENZ: Well, I do know. I can't make a plug
2 for them, but there is a commercial service that collects
3 that data.

4 MS. MELLON: Well, it isn't very satisfactory
5 either. Frankly, you know, being from the public interest
6 community, I want information that has the kind of authority
7 and credibility that would come from it coming from the
8 government. That would certainly be our preference. Thank
9 you.

10 CHAIRWOMAN LATHERS: Are there any other questions
11 at this moment?

12 (No response.)

13 CHAIRWOMAN LATHERS: If not, thank you Dan.

14 Our next speaker has just arrived, and I think we
15 will need a few minutes to load her PowerPoint slides. One
16 announcement that I have been asked to make is that Bill
17 Flynn is obtaining as many copies of the talks that we have
18 heard this morning as possible, and hopefully, copies will be
19 available for us this afternoon.

20 In addition, Bill anticipates that these will be on
21 the home page at a later date. So you will have hard copies
22 today and electronic copies in the future. Give us just a
23 moment, please.

24 (Pause.)

25 CHAIRWOMAN LATHERS: Our next speaker is Jean

1 Cooper. Jean is a 1987 graduate of the University of
2 Illinois Veterinary College. She does have a master's of
3 science in dairy microbiology and nutrition, and an
4 undergraduate degree in animal science, both earned at
5 Rutger's University.

6 She is, at this time, chief of the clinical
7 chemistry and toxicology branch at the Centers for Devices in
8 Radiological Health at the FDA. In her current position she
9 did work for the Center for Veterinary Medicine as an
10 application reviewer. In this capacity she reviewed the
11 studies supporting the 21 CFR 558.15 Regulation on the sub
12 therapeutic use of antimicrobial drugs in food products.

13 Jean.

14 **"558.15" STUDIES: A HISTORICAL PERSPECTIVE**

15 **By Dr. Jean Cooper**

16 DR. COOPER: Thank you. I had another meeting I
17 had to be at earlier, so that is why I didn't make it here
18 until now.

19 The Food and Drug Administration is the primary
20 federal agency responsible for insuring the safety in food
21 supply relative to the impact of drug use in food animals.
22 The Center for Vet Med approves animal drugs that are
23 effective and safe for animals and for consumers of animal
24 products from treated animals.

25 CVM considers the properties of each drug in
